European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

intro

Welcome

- ▶ Purpose of the course:
 - ▶ knowledge about APC-models
 - ▶ technical knowledge of handling them
 - ▶ insight in the basic concepts of analysis of rates
 - ▶ handling observation in the Lexis diagram
- ▶ Remedies of the course:
 - ▶ Lectures with handouts (BxC)
 - ▶ Practicals with suggested solutions (BxC)
 - ▶ Assignment for Thursday

Scope of the course

- ▶ Rates as observed in populations
— disease registers for example.
- ▶ Understanding of survival analysis (statistical analysis of rates)
— this is the content of much of the first day.
- ▶ Besides concepts, practical understanding of the actual computations (in **R**) are emphasized.
- ▶ There is a section in the practicals:
“Basic concepts of rates and survival”
— read it; use it as reference.
- ▶ If you are not quite familiar with matrix algebra in **R**, there is an intro on the course homepage.

About the lectures

- ▶ Please interrupt:
Most likely I did a mistake or left out a crucial argument.
- ▶ The handouts are not perfect
— please comment on them,
prospective students would benefit from it.
- ▶ Time-schedule:
Two lectures (≈ 2 hrs)
one practical (≈ 1 hr)

About the practicals

- ▶ You should use your preferred **R**-environment.
- ▶ Epi-package for **R** is needed, check that you have version 2.35
- ▶ Data are all on the course website.
- ▶ Try to make a text version of the answers to the exercises — it is more rewarding than just looking at output. The latter is soon forgotten — Rmd is a possibility.
- ▶ An opportunity to learn emacs, ESS and Sweave?

Rates and Survival

Bendix Carstensen

Statistical Analysis in the
Lexis Diagram:

Age-Period-Cohort models

— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

surv-rate

Survival data

- ▶ Persons enter the study at some date.
- ▶ Persons exit at a later date, either dead or alive.
- ▶ Observation:
 - ▶ Actual time span to death (“event”)
 - ▶ ... or ...
 - ▶ Some time alive (“at least this long”)

Examples of time-to-event measurements

- ▶ Time **from** diagnosis of cancer **to** death.
- ▶ Time **from** randomization **to** death in a cancer clinical trial
- ▶ Time **from** HIV infection **to** AIDS.
- ▶ Time **from** marriage **to** 1st child birth.
- ▶ Time **from** marriage **to** divorce.
- ▶ Time **from** jail release **to** re-offending

Each line a person

Each blob a death

Study ended at 31
Dec. 2003

Ordered by date of entry

Most likely the order in your database.

Timescale changed
to
“Time since
diagnosis”.

Patients ordered by survival time.

Survival times grouped into bands of survival.

Patients ordered by survival status within each band.

Survival after Cervix cancer

Year	Stage I			Stage II		
	<i>N</i>	<i>D</i>	<i>L</i>	<i>N</i>	<i>D</i>	<i>L</i>
1	110	5	5	234	24	3
2	100	7	7	207	27	11
3	86	7	7	169	31	9
4	72	3	8	129	17	7
5	61	0	7	105	7	13
6	54	2	10	85	6	6
7	42	3	6	73	5	6
8	33	0	5	62	3	10
9	28	0	4	49	2	13
10	24	1	8	34	4	6

Estimated risk in year 1 for Stage I women is $5/107.5 = 0.0465$

Estimated 1 year survival is $1 - 0.0465 = 0.9535$ — Life-table estimator.

Survival function

Persons enter at time 0:

Date of birth

Date of randomization

Date of diagnosis.

How **long** they survive, survival time T — a stochastic variable.

Distribution is characterized by the survival function:

$$\begin{aligned} S(t) &= P \{ \text{survival at least till } t \} \\ &= P \{ T > t \} = 1 - P \{ T \leq t \} = 1 - F(t) \end{aligned}$$

Intensity or rate

$$\begin{aligned}\lambda(t) &= P \{ \text{event in } (t, t + h] \mid \text{alive at } t \} / h \\ &= \frac{F(t + h) - F(t)}{S(t) \times h} \\ &= - \frac{S(t + h) - S(t)}{S(t)h} \xrightarrow{h \rightarrow 0} - \frac{d \log S(t)}{dt}\end{aligned}$$

This is the **intensity** or **hazard function** for the distribution.

Characterizes the survival distribution as does f or F .

Theoretical counterpart of a **rate**.

Empirical rates for individuals

- ▶ At the **individual** level we introduce the **empirical rate**: (d, y) ,
 - no. of events ($d \in \{0, 1\}$) during y risk time
- ▶ Each person may contribute several empirical (d, y)
- ▶ Empirical rates are **responses** in survival analysis
- ▶ The timescale is a **covariate**:
 - that varies between empirical rates from one individual:
Age, calendar time, time since diagnosis
- ▶ Do not confuse timescale with y — risk time (called exposure in demography)
a **difference** between two points on **any** timescale

Empirical rates by
calendar time.

Empirical rates by
time since diagnosis.

Two timescales

Note that we actually have two timescales:

- ▶ Time since diagnosis (*i.e.* since entry into the study)
- ▶ Calendar time.

These can be shown **simultaneously** in a Lexis diagram.

Follow-up by
calendar time *and*
time since diagnosis:

A Lexis
diagram!

Empirical rates by
calendar time *and*
time since diagnosis

So what's the purpose

- ▶ form the basis for statistical inference about occurrence rates:
- ▶ response: observed rates of events and person-time (d, y)
- ▶ covariates:
 - ▶ **A**: Age at follow-up
 - ▶ **P**: Period (date) of follow-up
 - ▶ **C**: (=P–A) Cohort (date of birth)

Likelihood for rates

Bendix Carstensen

Statistical Analysis in the
Lexis Diagram:

Age-Period-Cohort models

— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

likelihood

Likelihood contribution from one person

The likelihood from several empirical rates from one individual is a product of conditional probabilities:

$$\begin{aligned} P \{ \text{event at } t_4 \mid \text{alive at } t_0 \} &= P \{ \text{event at } t_4 \mid \text{alive at } t_3 \} \times \\ &P \{ \text{survive } (t_2, t_3) \mid \text{alive at } t_2 \} \times \\ &P \{ \text{survive } (t_1, t_2) \mid \text{alive at } t_1 \} \times \\ &P \{ \text{survive } (t_0, t_1) \mid \text{alive at } t_0 \} \end{aligned}$$

Likelihood contribution from one individual is a **product** of terms.

Each term refers to one empirical rate (d, y)

with $y = t_{i+1} - t_i$ (mostly $d = 0$).

t_i is a **covariate**

Likelihood for an empirical rate

- ▶ Likelihood depends on **data** and the **model**
- ▶ Model: the rate (λ) is constant in the interval.
- ▶ The interval should be sufficiently small for this assumption to be reasonable.

$$\begin{aligned}L(\lambda|y, d) &= P\{\text{survive } y\} \times P\{\text{event}\}^d \\ &= e^{-\lambda y} \times (\lambda dt)^d \\ &= \lambda^d e^{-\lambda y}\end{aligned}$$

$$\ell(\lambda|y, d) = d \log(\lambda) - \lambda y$$

Probability

$$P(d \text{ at } t_x | \text{entry } t_0)$$

$$= P(\text{surv } t_0 \rightarrow t_1 | \text{entry } t_0)$$

$$\times P(\text{surv } t_1 \rightarrow t_2 | \text{entry } t_1)$$

$$\times P(d \text{ at } t_x | \text{entry } t_2)$$

log-Likelihood

$$d \log(\lambda) - \lambda y$$

$$= 0 \log(\lambda) - \lambda y_1$$

$$+ 0 \log(\lambda) - \lambda y_2$$

$$+ d \log(\lambda) - \lambda y_3$$

Probability

$$P(\text{surv } t_0 \rightarrow t_x | \text{entry } t_0)$$

$$= P(\text{surv } t_0 \rightarrow t_1 | \text{entry } t_0)$$

$$\times P(\text{surv } t_1 \rightarrow t_2 | \text{entry } t_1)$$

$$\times P(\text{surv } t_2 \rightarrow t_x | \text{entry } t_2)$$

log-Likelihood

$$0 \log(\lambda) - \lambda y$$

$$= 0 \log(\lambda) - \lambda y_1$$

$$+ 0 \log(\lambda) - \lambda y_2$$

$$+ 0 \log(\lambda) - \lambda y_3$$

Probability

$P(\text{event at } t_x | \text{entry } t_0)$

$= P(\text{surv } t_0 \rightarrow t_1 | \text{entry } t_0)$

$\times P(\text{surv } t_1 \rightarrow t_2 | \text{entry } t_1)$

$\times P(\text{event at } t_x | \text{entry } t_2)$

log-Likelihood

$1 \log(\lambda) - \lambda y$

$= 0 \log(\lambda) - \lambda y_1$

$+ 0 \log(\lambda) - \lambda y_2$

$+ 1 \log(\lambda) - \lambda y_3$

Aim of dividing time into bands:

- ▶ Compute rates in different bands of:
 - ▶ age
 - ▶ calendar time
 - ▶ disease duration
 - ▶ ...
- ▶ Allow rates to vary along the timescale:

$$\begin{array}{l} 0 \log(\lambda) - \lambda y_1 \\ + 0 \log(\lambda) - \lambda y_2 \\ + d \log(\lambda) - \lambda y_3 \end{array} \quad \rightarrow \quad \begin{array}{l} 0 \log(\lambda_1) - \lambda_1 y_1 \\ + 0 \log(\lambda_2) - \lambda_2 y_2 \\ + d \log(\lambda_3) - \lambda_3 y_3 \end{array}$$

Log-likelihood from more persons

- ▶ One person p , different times t : $\sum_t (d_{pt} \log(\lambda_t) - \lambda_t y_{pt})$
- ▶ More persons: $\sum_p \sum_t (d_{pt} \log(\lambda_t) - \lambda_t y_{pt})$
- ▶ Collect terms with identical values of λ_t :

$$\begin{aligned} \sum_t \sum_p (d_{pt} \log(\lambda_t) - \lambda_t y_{pt}) &= \sum_t \left(\left(\sum_p d_{pt} \right) \log(\lambda_t) - \lambda_t \sum_p y_{pt} \right) \\ &= \sum_t \left(D_t \log(\lambda_t) - \lambda_t Y_t \right) \end{aligned}$$

- ▶ All events in interval t (“at” time t), D_t
- ▶ All exposure time in interval t (“at” time t), Y_t

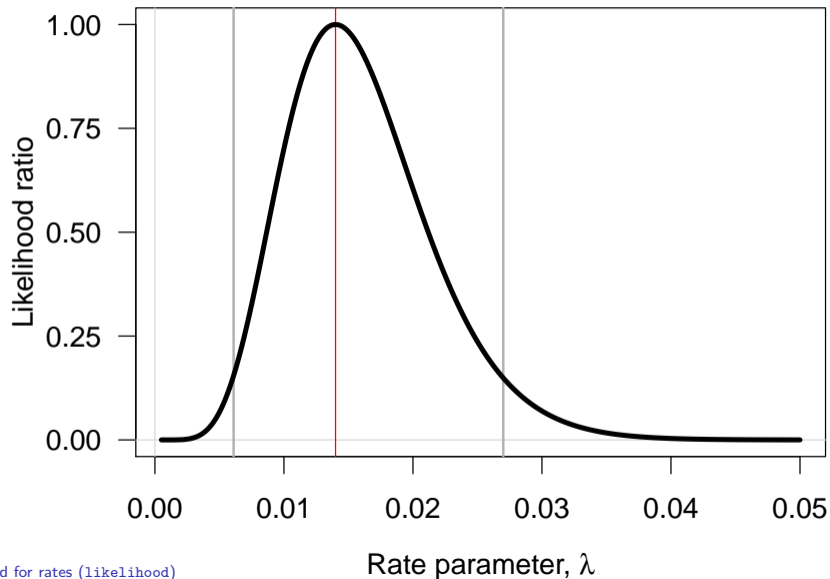

Likelihood example

- ▶ Assuming the rate (intensity) is constant, λ ,
- ▶ the probability of observing 7 deaths in the course of 500 person-years:

$$\begin{aligned}P\{D = 7, Y = 500|\lambda\} &= \lambda^D e^{-\lambda Y} \times K \\ &= \lambda^7 e^{-\lambda 500} \times K \\ &= L(\lambda|\text{data})\end{aligned}$$

- ▶ Best guess of λ is where this function is as large as possible.
- ▶ Confidence interval is where it is not too far from the maximum

Likelihood-ratio function

Log-likelihood ratio

Log-likelihood ratio

Log-likelihood ratio

Log-likelihood ratio

Log-likelihood ratio

$$\hat{\lambda} = 7/500 = 14$$

$$\hat{\lambda}^{\times} \div \exp(1.96/\sqrt{7}) = (6.7, 29.4)$$

Poisson likelihood

Log-likelihood from **follow-up** of **one individual**, p , in interval t :

$$\ell_{\text{FU}}(\lambda|d, y) = d_{pt} \log(\lambda(t)) - \lambda(t)y_{pt}, \quad t = 1, \dots, t_p$$

Log-likelihood from a **Poisson observation** d_{pt} with mean $\mu = \lambda(t)y_{pt}$:

$$\begin{aligned} \ell_{\text{Poisson}}(\lambda \mathbf{y}|d) &= d_{pt} \log(\lambda(t) \mathbf{y}_{pt}) - \lambda(t)y_{pt} \\ &= \ell_{\text{FU}}(\lambda|d, y) + d_{pt} \log(\mathbf{y}_{pt}) \end{aligned}$$

Extra term does not depend on the rate parameter λ .

Poisson likelihood

Log-likelihood contribution from **one** individual, p , say, is:

$$\ell_{\text{FU}}(\lambda|d, y) = \sum_t (d_{pt} \log(\lambda(t)) - \lambda(t) y_{pt})$$

- ▶ The terms in the sum are **not** independent,
 - ▶ but the log-likelihood is a **sum** of Poisson-like terms,
 - ▶ the **same** as a likelihood for **independent** Poisson variates, d_{pt}
 - ▶ with mean $\mu = \lambda_t y_{pt} \Leftrightarrow \log \mu = \log(\lambda_t) + \log(y_{pt})$
- ⇒ Analyze rates λ based on empirical rates (d, y) as a Poisson model for independent variates where:
- ▶ d_{pt} is the response variable.
 - ▶ $\log(y_{pt})$ is the offset variable.

Likelihood for follow-up of many subjects

Adding empirical rates over the follow-up of persons:

$$D = \sum d \quad Y = \sum y \quad \Rightarrow \quad D \log(\lambda) - \lambda Y$$

- ▶ Persons are assumed independent
- ▶ Contribution from the same person are **conditionally** independent, hence give separate contributions to the log-likelihood.
- ▶ Follow-up **model** and Poisson **model** are different
- ▶ ... but the **likelihoods** are the same.

The log-likelihood is maximal for:

$$\frac{d\ell(\lambda)}{d\lambda} = \frac{D}{\lambda} - Y = 0 \quad \Leftrightarrow \quad \hat{\lambda} = \frac{D}{Y}$$

Information about the log-rate $\theta = \log(\lambda)$:

$$\ell(\theta|D, Y) = D\theta - e^\theta Y, \quad \ell'_\theta = D - e^\theta Y, \quad \ell''_\theta = -e^\theta Y$$

so $I(\hat{\theta}) = e^{\hat{\theta}} Y = \hat{\lambda} Y = D$, hence $\text{var}(\hat{\theta}) = 1/D$

Standard error of log-rate: $1/\sqrt{D}$.

Note that this only depends on the no. events, **not** on the follow-up time.

The log-likelihood is maximal for:

$$\frac{d\ell(\lambda)}{d\lambda} = \frac{D}{\lambda} - Y = 0 \quad \Leftrightarrow \quad \hat{\lambda} = \frac{D}{Y}$$

Information about the rate itself, λ :

$$\ell(\lambda|D, Y) = D\log(\lambda) - \lambda Y \quad \ell'_{\lambda} = \frac{D}{\lambda} - Y \quad \ell''_{\lambda} = -\frac{D}{\lambda^2}$$

so $I(\hat{\lambda}) = D/\hat{\lambda}^2 = Y^2/D$, hence $\text{var}(\hat{\lambda}) = D/Y^2$

Standard error of a rate: \sqrt{D}/Y .

Confidence interval for a rate

A 95% confidence interval for the log of a rate is:

$$\hat{\theta} \pm 1.96/\sqrt{D} = \log(\lambda) \pm 1.96/\sqrt{D}$$

Take the exponential to get the confidence interval for the rate:

$$\lambda \times \underbrace{\exp(1.96/\sqrt{D})}_{\text{error factor, erf}}$$

Alternatively do the c.i. directly on the rate scale:

$$\lambda \pm 1.96\sqrt{D}/Y$$

Exercise

Suppose we have 17 deaths during 843.6 years of follow-up.
Calculate the mortality rate with a 95% c.i.

Rates with glm

```
> library(Epi)
> D <- 17
> Y <- 843.6/1000
> round( ci.exp( glm( D ~ 1, offset=log(Y), family=poisson ) ), 2 )

              exp(Est.)  2.5% 97.5%
(Intercept)    20.15 12.53 32.42

> round( ci.exp( glm( D/Y ~ 1, weight=      Y , family=poisson ) ), 2 )

              exp(Est.)  2.5% 97.5%
(Intercept)    20.15 12.53 32.42

> round( ci.exp( glm( D/Y ~ 1, weight=      Y , family=poisson(link="identity")),
+           Exp=FALSE), 2 )

              Estimate  2.5% 97.5%
(Intercept)    20.15 10.57 29.73
```

Ratio of two rates

If we have observations two rates λ_1 and λ_0 , based on (D_1, Y_1) and (D_0, Y_0) the variance of the log of the ratio of the rates, $\log(\text{RR})$, is:

$$\begin{aligned}\text{var}(\log(\text{RR})) &= \text{var}(\log(\lambda_1/\lambda_0)) \\ &= \text{var}(\log(\lambda_1)) + \text{var}(\log(\lambda_0)) \\ &= 1/D_1 + 1/D_0\end{aligned}$$

As before, a 95% c.i. for the RR is then:

$$\text{RR} \times \underbrace{\exp\left(1.96\sqrt{\frac{1}{D_1} + \frac{1}{D_0}}\right)}_{\text{error factor}}$$

Exercise

Suppose we in group 0 have 17 deaths during 843.6 years of follow-up in one group, and in group 1 have 28 deaths during 632.3 years.

Calculate the rate-ratio between group 1 and 0 with a 95% c.i.

Rate-ratio with glm

```
> library(Epi)
> D <- c(17,28)
> Y <- c(843.6,632.3)/1000
> F <- factor(0:1)
> round( ci.exp( glm( D ~ F, offset=log(Y), family=poisson ) ), 2 )
```

	exp(Est.)	2.5%	97.5%
(Intercept)	20.15	12.53	32.42
F1	2.20	1.20	4.01

```
> round( ci.exp( glm( D ~ F - 1, offset=log(Y), family=poisson ) ), 2 )
```

	exp(Est.)	2.5%	97.5%
F0	20.15	12.53	32.42
F1	44.28	30.58	64.14

Rate-ratio and -difference with glm

```
> round( ci.exp( glm( D/Y ~ F      , weight=Y, family=poisson ) ), 2 )
```

```
              exp(Est.)  2.5% 97.5%
(Intercept)    20.15 12.53 32.42
F1              2.20  1.20  4.01
```

```
> round( ci.exp( glm( D/Y ~ F      , weight=Y, family=poisson(link="identity")),
+              Exp=FALSE), 2 )
```

```
              Estimate  2.5% 97.5%
(Intercept)    20.15 10.57 29.73
F1              24.13  5.14 43.13
```

```
> round( ci.exp( glm( D/Y ~ F - 1, weight=Y, family=poisson(link="identity")),
+              Exp=FALSE), 2 )
```

```
              Estimate  2.5% 97.5%
F0           20.15 10.57 29.73
F1           44.28 27.88 60.69
```

Lifetables

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

lifetable

The life table method

The simplest analysis is by the “life-table method”:

interval	alive	dead	cens.	
i	n_i	d_i	l_i	p_i
1	77	5	2	$5/(77 - 2/2) = 0.066$
2	70	7	4	$7/(70 - 4/2) = 0.103$
3	59	8	1	$8/(59 - 1/2) = 0.137$

$$p_i = P \{ \text{death in interval } i \} = 1 - d_i / (n_i - l_i / 2)$$
$$S(t) = (1 - p_1) \times \cdots \times (1 - p_t)$$

The life table method

The life-table method computes survival probabilities for each time interval, in demography normally one year.

The rate is the number of deaths d_i divided by the risk time $(n_i - d_i/2 - l_i/2) \times \ell_i$:

$$\lambda_i = \frac{d_i}{(n_i - d_i/2 - l_i/2) \times \ell_i}$$

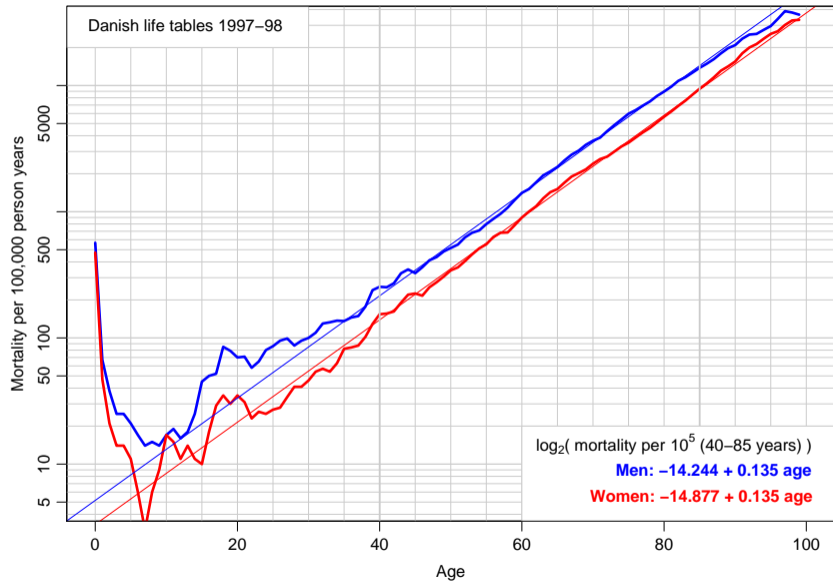

and hence the death probability:

$$p_i = 1 - \exp - \lambda_i \ell_i = 1 - \exp \left(- \frac{d_i}{(n_i - d_i/2 - l_i/2)} \right)$$

The modified life-table estimator.

Population life table, DK 1997–98

Practical

Based on the previous slides answer the following for both Danish and Swedish life tables:

- ▶ What is the doubling time for mortality?
- ▶ What is the rate-ratio between males and females?
- ▶ How much older should a woman be in order to have the same mortality as a man?

Denmark	Males	Females
$\log_2(\lambda(a))$	$-14.244 + 0.135 \text{ age}$	$-14.877 + 0.135 \text{ age}$
Doubling time	$1/0.135 = 7.41 \text{ years}$	
M/F rate-ratio	$2^{-14.244+14.877} = 2^{0.633} = 1.55$	
Age-difference	$(-14.244 + 14.877)/0.135 = 4.69 \text{ years}$	

Sweden:	Males	Females
$\log_2(\lambda(a))$	$-15.453 + 0.146 \text{ age}$	$-16.204 + 0.146 \text{ age}$
Doubling time	$1/0.146 = 6.85 \text{ years}$	
M/F rate-ratio	$2^{-15.453+16.204} = 2^{0.751} = 1.68$	
Age-difference	$(-15.453 + 16.204)/0.146 = 5.14 \text{ years}$	

Observations for the lifetable

Life table is based on person-years and deaths accumulated in a short period.

Age-specific rates — cross-sectional!

Survival function:

$$S(t) = e^{-\int_0^t \lambda(a) da} = e^{-\sum_0^t \lambda(a)}$$

— assumes stability of rates to be interpretable for actual persons.

Life table approach

The observation of interest is **not** the survival time of the **individual**.

It is the **population** experience:

D: Deaths (events).

Y: Person-years (risk time).

The classical lifetable analysis compiles these for prespecified intervals of age, and computes age-specific mortality **rates**.

Data are collected cross-sectionally, but interpreted longitudinally.

Rates vary over time:

Rates vary over time:

Rates vary over time:

Who needs the Cox-model anyway?

<http://BendixCarstensen/APC/EDSD-2019>

A look at the Cox model

$$\lambda(t, x) = \lambda_0(t) \times \exp(x'\beta)$$

A model for the rate as a function of t and x .

Covariates:

- ▶ x
- ▶ t
- ▶ ... often the effect of t is ignored (forgotten?)
- ▶ *i.e.* left unreported

The Cox-likelihood as profile likelihood

- ▶ One parameter per death time to describe the effect of time (i.e. the chosen timescale).

$$\log(\lambda(t, x_i)) = \log(\lambda_0(t)) + \underbrace{\beta_1 x_{1i} + \dots + \beta_p x_{pi}}_{\eta_i} = \alpha_t + \eta_i$$

- ▶ Profile likelihood:
 - ▶ Derive estimates of α_t as function of data and β s
 - assuming constant rate between death/censoring times
 - ▶ Insert in likelihood, now only a function of data and β s
 - ▶ This turns out to be Cox's partial likelihood
- ▶ Cumulative intensity ($\Lambda_0(t)$) obtained via the Breslow-estimator

Mayo Clinic lung cancer data: 60 year old woman

Splitting the dataset a priori

- ▶ The Poisson approach needs a dataset of empirical rates (d, y) with suitably small values of y .
- ▶ — each individual contributes many empirical rates
- ▶ (one per risk-set contribution in Cox-modeling)
- ▶ From each empirical rate we get:
 - ▶ Poisson-response d
 - ▶ Risk time $y \rightarrow \log(y)$ as offset
 - ▶ time scale covariates: current age, current date, ...
 - ▶ other covariates
- ▶ Contributions not independent, but likelihood is a product
- ▶ Same likelihood as for independent Poisson variates
- ▶ Poisson `glm` with spline/factor effect of time

Example: Mayo Clinic lung cancer

- ▶ Survival after lung cancer
- ▶ Covariates:
 - ▶ Age at diagnosis
 - ▶ Sex
 - ▶ Time since diagnosis
- ▶ Cox model
- ▶ Split data:
 - ▶ Poisson model, time as factor
 - ▶ Poisson model, time as spline

Mayo Clinic lung cancer 60 year old woman

Example: Mayo Clinic lung cancer I

```
> library( survival )
> library( Epi )
> Lung <- Lexis( exit = list( tfe=time ),
+               exit.status = factor(status,labels=c("Alive","Dead")),
+               data = lung )
```

NOTE: entry.status has been set to "Alive" for all.

NOTE: entry is assumed to be 0 on the tfe timescale.

```
> summary( Lung )
```

Deriving the survival function

```
> mLs.pois.sp <- glm( lex.Xst=="Dead" ~ Ns( tfe, knots=t.kn ) +
+                   age + factor( sex ),
+                   offset = log(lex.dur),
+                   family=poisson, data=Lung.s, eps=10^-8, maxit=25 )

> CM <- cbind( 1, Ns( seq(10,1000,10)-5, knots=t.kn ), 60, 1 )
> lambda <- ci.exp( mLs.pois.sp, ctr.mat=CM )
> Lambda <- ci.cum( mLs.pois.sp, ctr.mat=CM, intl=10 )[, -4]
> survP <- exp(-rbind(0, Lambda))
```

Code and output for the entire example available in
<http://bendixcarstensen.com/AdvCoh/WNtCMA/>

What the Cox-model really is

Taking the life-table approach *ad absurdum* by:

- ▶ dividing time very finely and
- ▶ modeling one covariate, the time-scale, with one parameter per distinct value.
- ▶ the **model** for the time scale is really with exchangeable time-intervals.
- ⇒ difficult to access the baseline hazard (which looks terrible)
- ⇒ uninitiated tempted to show survival curves where irrelevant

Code and output for the entire example available in
<http://bendixcarstensen.com/AdvCoh/WNtCMA/>

Models of this world

- ▶ Replace the α_t s by a parametric function $f(t)$ with a limited number of parameters, for example:
 - ▶ Piecewise constant
 - ▶ Splines (linear, quadratic or cubic)
 - ▶ Fractional polynomials
- ▶ the two latter brings model into “this world”:
 - ▶ smoothly varying rates
 - ▶ parametric closed form representation of baseline hazard
 - ▶ finite no. of parameters
- ▶ Makes it really easy to use rates directly in calculations of
 - ▶ expected residual life time
 - ▶ state occupancy probabilities in multistate models
 - ▶ ...

Follow-up data

Statistical Analysis in the
Lexis Diagram:

Age-Period-Cohort models

— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

time-split

Follow-up and rates

- ▶ In follow-up studies we estimate rates from:
 - ▶ D — events, deaths
 - ▶ Y — person-years
 - ▶ $\hat{\lambda} = D/Y$ rates
 - ▶ ... empirical counterpart of intensity — **estimate**
- ▶ Rates differ between persons.
- ▶ Rates differ **within** persons:
 - ▶ By age
 - ▶ By calendar time
 - ▶ By disease duration
 - ▶ ...
- ▶ Multiple timescales.
- ▶ Multiple states (little boxes — later)

Examples: stratification by age

If follow-up is rather short, age at entry is OK for age-stratification.

If follow-up is long, use stratification by categories of **current age**, both for:

No. of events, D , and Risk time, Y .

— assuming a constant rate λ throughout.

Representation of follow-up data

A cohort or follow-up study records:

Events and **Risk time**.

The outcome is thus **bivariate**: (d, y)

Follow-up **data** for each individual must therefore have (at least) three variables:

Date of entry	entry	date variable
Date of exit	exit	date variable
Status at exit	fail	indicator (0/1)

Specific for each **type** of outcome.

Probability

$$P(d \text{ at } t_x | \text{entry } t_0)$$

$$= P(\text{surv } t_0 \rightarrow t_1 | \text{entry } t_0)$$

$$\times P(\text{surv } t_1 \rightarrow t_2 | \text{entry } t_1)$$

$$\times P(d \text{ at } t_x | \text{entry } t_2)$$

log-Likelihood

$$d \log(\lambda) - \lambda y$$

$$= 0 \log(\lambda_1) - \lambda_1 y_1$$

$$+ 0 \log(\lambda_2) - \lambda_2 y_2$$

$$+ d \log(\lambda_3) - \lambda_3 y_3$$

— allows different rates (λ_i) in each interval

Dividing time into bands:

If we want to compute D and Y in intervals on some timescale we must decide on:

Origin: The date where the time scale is 0:

- ▶ Age — 0 at date of birth
- ▶ Disease duration — 0 at date of diagnosis
- ▶ Occupation exposure — 0 at date of hire

Intervals: How should it be subdivided:

- ▶ 1-year classes? 5-year classes?
- ▶ Equal length?

Aim: Separate rate in each interval

Example: cohort with 3 persons:

Id	Bdate	Entry	Exit	St
1	14/07/1952	04/08/1965	27/06/1997	1
2	01/04/1954	08/09/1972	23/05/1995	0
3	10/06/1987	23/12/1991	24/07/1998	1

- ▶ Age bands: 10-years intervals of current age.
- ▶ Split Y for every subject accordingly
- ▶ Treat each segment as a separate unit of observation.
- ▶ Keep track of exit status in each interval.

Splitting the follow up

	subj. 1	subj. 2	subj. 3

2	01/04/1954	31/03/1984	01/04/1994	0	10.0000	30
2	01/04/1954	01/04/1994	23/05/1995	0	1.1417	40
3	10/06/1987	23/12/1991	09/06/1997	0	5.4634	0
3	10/06/1987	09/06/1997	24/07/1998	1	1.1211	10

Keeping track of calendar time too?

Timescales

- ▶ A timescale is a variable that varies **deterministically** *within* each person during follow-up:
 - ▶ Age
 - ▶ Calendar time
 - ▶ Time since treatment
 - ▶ Time since relapse
- ▶ All timescales advance at the same pace (1 year per year . . .)
- ▶ Note: Cumulative exposure is **not** a timescale.

Follow-up on several timescales

- ▶ The risk-time is the same on all timescales
- ▶ Only need the entry point on each time scale:
 - ▶ Age at entry.
 - ▶ Date of entry.
 - ▶ Time since treatment at entry.
 - if time of treatment is the entry, this is 0 for all.

- ▶ **Response variable** in analysis of rates:

(d, y) (**event, duration**)

- ▶ **Covariates** in analysis of rates:
 - ▶ **timescales**
 - ▶ other (fixed) measurements
- ▶ ... do not confuse **duration** and **timescale** !

Follow-up data in Epi — Lexis objects

```
> thoro[1:6,1:8]
```

	id	sex	birthdat	contrast	injecdat	volume	exitdat	exitstat
1	1	2	1916.609	1	1938.791	22	1976.787	1
2	2	2	1927.843	1	1943.906	80	1966.030	1
3	3	1	1902.778	1	1935.629	10	1959.719	1
4	4	1	1918.359	1	1936.396	10	1977.307	1
5	5	1	1902.931	1	1937.387	10	1945.387	1
6	6	2	1903.714	1	1937.316	20	1944.738	1

Timescales of interest:

- ▶ Age
- ▶ Calendar time
- ▶ Time since injection

Definition of Lexis object

```
thL <- Lexis( entry = list( age = injecdat-birthdat,  
                           per = injecdat,  
                           tfi = 0 ),  
             exit = list( per = exitdat ),  
             exit.status = as.numeric(exitstat==1),  
             data = thoro )
```

entry is defined on **three** timescales,

but **exit** is only needed on **one** timescale:

Follow-up time is the same on all timescales:

`exitdat - injecdat`

One element of **entry** and **exit** must have same name (**per**).

The looks of a Lexis object

```
> thL[1:4,1:9]
  age      per tfi lex.dur lex.Cst lex.Xst lex.id

Likelihood for a constant rate

- ▶ This setup is for a situation where it is assumed that rates are constant in each of the intervals.
- ▶ Each observation in the dataset contributes a term to the likelihood.
- ▶ Each term looks like a contribution from a Poisson variate (albeit with values only 0 or 1)
- ▶ Rates can vary along several timescales simultaneously.
- ▶ Models can include fixed covariates, as well as the timescales (the left end-points of the intervals) as **quantitative** variables.
- ▶ The latter is where we will need splines.

The Poisson likelihood for split data

- ▶ Split records (one per **person-interval** (p, i)):

$$\sum_{p,i} (d_{pi} \log(\lambda) - \lambda y_{pi}) = D \log(\lambda) - \lambda Y$$

- ▶ Assuming that the death indicator ($d_{pi} \in \{0, 1\}$) is Poisson, a model with with offset $\log(y_{pi})$ will give the same result.
- ▶ If we assume that rates are constant we get the simple expression with (D, Y)
- ▶ ... but the split data allows models that assume different rates for different (d_{pi}, y_{pi}) , so rates can vary **within** a person's follow-up.

Where is (d_{pi}, y_{pi}) in the split data?

```
> spl1 <- splitLexis( thL , breaks=seq(0,100,20) , time.scale="age" )
> spl2 <- splitLexis( spl1, breaks=c(0,1,5,20,100), time.scale="tfi" )
> options( digits=5 )
> spl2[1:10,1:11]
```

— not the printing: it's a data.table

Analysis of results

- ▶ d_{pi} — events in the variable: `lex.Xst`:
In the model as response: `lex.Xst==1`
- ▶ y_{pi} — risk time: `lex.dur` (duration):
In the model as offset `log(y)`, `log(lex.dur)`.
- ▶ Covariates are:
 - ▶ timescales (age, period, time in study)
 - ▶ other variables for this person (constant or *assumed* constant in each interval).
- ▶ Model rates using the covariates in `glm`:
— no difference between time-scales and other covariates.

Fitting a simple model

```
> stat.table( contrast,  
+             list( D = sum( lex.Xst ),  
+                 Y = sum( lex.dur ),  
+                 Rate = ratio( lex.Xst, lex.dur, 100 ) ),  
+             margin = TRUE,  
+             data = spl2 )
```

contrast	D	Y	Rate
1	928.00	20094.74	4.62
2	1036.00	31822.24	3.26
Total	1964.00	51916.98	3.78

Fitting a simple model

contrast	D	Y	Rate
1	928.00	20094.74	4.62

Statistical Analysis in the
Lexis Diagram:

Age-Period-Cohort models

— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

tab-mod

Conceptual set-up

Follow-up of the entire (male) population from 1943–2006 w.r.t. occurrence of testis cancer:

- ▶ Split follow-up time for all about 4 mil. men in 1-year classes by age and calendar time (y).
- ▶ Allocate testis cancer event ($d = 0, 1$) to each.
- ▶ Analyze all 200,000,000 records by a Poisson model.

Realistic set-up

- ▶ Tabulate the follow-up time and events by age and period.
- ▶ 100 age-classes.
- ▶ 65 periods (single calendar years).
- ▶ 6500 aggregate records of (D, Y) .
- ▶ Analyze by a Poisson model.

Practical set-up

- ▶ Tabulate only events (as obtained from the cancer registry) by age and period.
- ▶ 100 age-classes.
- ▶ 65 periods (single calendar years).
- ▶ 6500 aggregate records of D .
- ▶ Estimate the population follow-up based on census data from Statistics Denmark (Y_{pop}).
... or get it from the human mortality database.
- ▶ If disease is common: tabulate follow-up **after** diagnosis (Y_{dis}), and subtract from population follow-up.
- ▶ Analyze (D, Y) by Poisson model.

Lexis diagram ¹

Disease registers record events.

Official statistics collect population data.

¹ Named after the German statistician and economist **William Lexis** (1837–1914), who devised this diagram in the book “Einleitung in die Theorie der Bevölkerungsstatistik” (Karl J. Trübner, Strassburg, 1875).

Lexis diagram

Registration of:

cases (D)

risk time,
person-years (Y)

in subsets of the Lexis
diagram.

Lexis diagram

Registration of:

cases (D)

risk time,
person-years (Y)

in subsets of the Lexis
diagram.

Rates available in each
subset.

Register data

Classification of **cases** (D_{ap}) by age at diagnosis and date of diagnosis, and **population** (Y_{ap}) by age at risk and date at risk, in compartments of the Lexis diagram, e.g.:

```
> fCtable( xtabs( cbind(D,Y) ~ A + P, data=ts ), col.vars=3:2, w=8 )
```

	D				Y			
P	1943	1948	1953	1958	1943	1948	1953	1958

16 30 1953 49 769298
17 35 1953 39 760213
18 40 1953 46 768471
19 15 1958  1 072852
```

Tabulated data

Once data are in tabular form, models are restricted:

- ▶ Rates must be assumed constant in each cell of the table / subset of the Lexis diagram.
- ▶ With large cells (5×5 years) it is customary to put a separate parameter on each cell or on each levels of classifying factors.
- ▶ Output from the model will be rates and rate-ratios.
- ▶ Since we use multiplicative Poisson, usually the log rates and the log-RR are reported

Simple age-period model for the testis cancer rates:

```
> m0 <- glm( D ~ factor(A) + factor(P) + offset( log(Y/10^5) ),  
+           family=poisson, data=ts )  
> summary( m0 )
```

Call:

```
glm(formula = D ~ factor(A) + factor(P) + offset(log(Y/10^5)),  
     family = poisson, data = ts)
```

Deviance Residuals:

Min	1Q	Median	3Q	Max
-1.5991	-0.6974	0.1284	0.6671	1.8904

Coefficients:

	Estimate	Std. Error	z value	Pr(> z)
(Intercept)	-1.4758	0.3267	-4.517	6.26e-06
factor(A)20	1.4539	0.3545	4.101	4.11e-05
factor(A)25	2.5321	0.3301	7.671	1.71e-14
factor(A)30	2.9327	0.3254	9.013	< 2e-16
factor(A)35	2.8613	0.3259	8.779	< 2e-16
factor(A)40	2.8521	0.3263	8.741	< 2e-16
factor(P)1948	0.1753	0.1211	1.447	0.14778
factor(P)1953	0.3822	0.1163	3.286	0.00102

`ci.exp()` from the `Epi` package extracts coefficients and computes confidence intervals:

```
> round( ci.exp( m0 ), 2 )
```

	exp(Est.)	2.5%	97.5%
(Intercept)	0.23	0.12	0.43
factor(A)20	4.28	2.14	8.57
factor(A)25	12.58	6.59	24.02
factor(A)30	18.78	9.92	35.53
factor(A)35	17.49	9.23	33.12
factor(A)40	17.32	9.14	32.84
factor(P)1948	1.19	0.94	1.51
factor(P)1953	1.47	1.17	1.84
factor(P)1958	1.59	1.27	2.00

... what do these parameters mean?

Subsets of parameter estimates accessed via a character string that is grep-ed to the names.

```
> round( ci.exp( m0, subset="P", pval=TRUE ), 3 )
```

	exp(Est.)	2.5%	97.5%	P
factor(P)1948	1.192	0.940	1.511	0.148
factor(P)1953	1.466	1.167	1.841	0.001
factor(P)1958	1.593	1.272	1.996	0.000

```
> round( ci.lin( m0, subset="P" ), 3 )
```

	Estimate	StdErr	z	P	2.5%	97.5%
factor(P)1948	0.175	0.121	1.447	0.148	-0.062	0.413
factor(P)1953	0.382	0.116	3.286	0.001	0.154	0.610
factor(P)1958	0.466	0.115	4.052	0.000	0.241	0.691

Linear combinations of the parameters can be computed using the `ctr.mat` option:

```
> CM <- rbind( '1943 vs. 1953' = c( 0,-1, 0),  
+             '1948 vs. 1953' = c( 1,-1, 0),  
+             'Ref. (1953)'   = c( 0, 0, 0),  
+             '1958 vs. 1953' = c( 0,-1, 1) )  
> round( ci.exp( m0, subset="P", ctr.mat=CM ), 3 )
```

	exp(Est.)	2.5%	97.5%
1943 vs. 1953	0.682	0.543	0.857
1948 vs. 1953	0.813	0.655	1.010
Ref. (1953)	1.000	1.000	1.000
1958 vs. 1953	1.087	0.887	1.332

Age-Period and Age-Cohort models

AP-AC

Register data — rates

Rates in “tiles” of the Lexis diagram:

$$\lambda(a, p) = D_{ap} / Y_{ap}$$

Descriptive epidemiology based on disease registers:

How do the rates vary by age and time:

- ▶ Age-specific rates for a given period.
- ▶ Age-standardized rates as a function of calendar time.
(Weighted averages of the age-specific rates).

“Synthetic” cohorts

Events and risk time in cells along the diagonals are among persons with roughly same date of birth.

Successively overlapping 10-year periods.

Lexis diagram: data

Testis cancer cases in Denmark.

The classical plots

Given a table of rates classified by age and period, we can do 4 “classical” plots:

- ▶ Rates versus age at diagnosis (period):
 - rates in the same age-class connected.
- ▶ Rates versus age at diagnosis:
 - rates in the same birth-cohort connected.
- ▶ Rates versus date of diagnosis:
 - rates in the same age-class connected.
- ▶ Rates versus date of date of birth:
 - rates in the same age-class connected.

These plots can be produced by the R-function `rateplot`.

```
> library( Epi )  
> data( testisDK )  
> head( testisDK )
```

Age-Period model

Rates are proportional between periods:

$$\lambda(a, p) = a_a \times b_p \quad \text{or} \quad \log[\lambda(a, p)] = \alpha_a + \beta_p$$

Choose p_0 as reference period, where $\beta_{p_0} = 0$

$$\log[\lambda(a, p_0)] = \alpha_a + \beta_{p_0} = \alpha_a$$

Fitting the A-P model in R I

Reference period is the 5th period (1970.5 ~ 1968–72):

```
> ap <- glm( D ~ factor(A) - 1 + relevel( factor(P), "1970.5" ) +  
+         offset( log(Y/10^5) ),  
+         family=poisson, data=ts )  
> summary( ap )
```

Call:

```
glm(formula = D ~ factor(A) - 1 + relevel(factor(P), "1970.5") +  
    offset(log(Y/10^5)), family = poisson, data = ts)
```

Estimates from Age-Cohort model

Recap of Monday — rates

- ▶ Rate, intensity: $\lambda(t) = P \{ \text{event in } (t, t + h) | \text{alive at } t \} / h$
- ▶ Observe empirical rates (d, y) — possibly many per person.
- ▶ $\ell_{\text{FU}} = d \log(\lambda) - \lambda y$, obs: (d, y) , rate par: λ
- ▶ $\ell_{\text{Poisson}} = d \log(\lambda y) - \lambda y$, obs: d , mean par: $\mu = \lambda y$
- ▶ $\ell_{\text{Poisson}} - \ell_{\text{FU}} = d \log(y)$ does not involve λ
— use either to find m.l.e. of λ
- ▶ Poisson model is for $\log(\mu) = \log(\lambda y) = \log(\lambda) + \log(y)$
hence offset = $\log(Y)$
- ▶ Once rates are known, we can construct survival curves and derivatives of that.

Recap Monday — models

- ▶ Empirical rate (d_t, y_t) relates to a **time** t
- ▶ Many for the same person — different times
- ▶ Not independent, but likelihood is a product
- ▶ One parameter per interval \Rightarrow exchangeable times
- ▶ Use the quantitative nature of t : \Rightarrow smooth continuous effects of time
- ▶ Predicted rates: `ci.pred(model, newdata=nd)`
- ▶ RR is the difference between two predictions:
- ▶ RR by period:
 - ▶ `ndx<-data.frame(P=1947:1980,A=47)`
 - ▶ `ndr<-data.frame(P=1870,A=47)`
 - ▶ `ci.exp(model, ctr.mat=list(ndx-ndr))`

factor(A)57.5	-2.64527	0.06423	-41.19	<2e-16
I(C - 1933)	0.02653	0.00100	26.52	<2e-16

(Dispersion parameter for poisson family taken to be 1)

Null deviance:	89358.53	on 81	degrees of freedom
Residual deviance:	126.07	on 71	degrees of freedom

What goes on?

$$p = a + c \quad p_0 = a_0 + c_0$$

$$\begin{aligned} \alpha_a + \beta(p - p_0) &= \alpha_a + \beta(a + c - (a_0 + c_0)) \\ &= \underbrace{\alpha_a + \beta(a - a_0)}_{\text{cohort age-effect}} + \beta(c - c_0) \end{aligned}$$

The two **models** are the same.

The **parametrization** is different.

The age-curve refers either

- to a period (cross-sectional rates) or
- to a cohort (longitudinal rates).

Which age-curve is period and which is cohort?

Fitting the model in R V

No. of parameters

A has $9(A)$ levels

P has $10(P)$ levels

C=P-A has $18(C = A + P - 1)$ levels

Age-drift model has $A + 1 = 10$ parameters

Age-period model has $A + P - 1 = 18$ parameters

Age-cohort model has $A + C - 1 = 26$ parameters

Age-period-cohort model has $A + P + C - 3 = 34$ parameters:

```
> length( coef(m.apc) ) ; sum( !is.na(coef(m.apc)) )
```

```
[1] 35
```

```
[1] 34
```

The missing parameter is because of the **identifiability problem**.

Test for effects

```
> tc.acp <- apc.fit( tc, model="factor", ref.c=1943, scale=10^5 )

Analysis of deviance for Age-Period-Cohort model
```

	Resid. Df	Resid. Dev	Df	Deviance	Pr(>Chi)
Age	81	1114.65			
Age-drift	80	131.77	1	982.88	< 2.2e-16
Age-Cohort	64	70.20	16	61.57	2.84e-07
Age-Period-Cohort	56	38.78	8	31.42	0.0001183
Age-Period	72	122.23	-16	-83.45	3.95e-11
Age-drift	80	131.77	-8	-9.54	0.2989863

How to choose a parametrization

- ▶ Standard approach: Put extremes of periods or cohorts to 0, and choose a reference for the other.
- ▶ Clayton & Schifflers: only 2nd order differences are invariants:

$$\alpha_{i-1} - 2\alpha_i + \alpha_{i+1}$$

Implemented in Epi via the contrast type `contr.2nd` (later).

- ▶ Holford: Extract linear effects by regression:

$$\lambda(a, p) = \hat{\alpha}_a + \hat{\beta}_p + \hat{\gamma}_c = \tilde{\alpha}_a + \tilde{\beta}_p + \tilde{\gamma}_c + \hat{\mu}_a + \hat{\mu}_p + \hat{\mu}_c + \hat{\delta}_a a + \hat{\delta}_p p + \hat{\delta}_c c$$

Assumptions

Assumptions are needed to do this, *e.g.*:

- ▶ Age is the major time scale
- ▶ Cohort is the secondary time scale (the major secular trend)
- ▶ c_0 is the reference cohort
- ▶ Period is the residual time scale: 0 on average, 0 slope
- ▶ ... constraining first and last period parameter to 0 is a crude way of obtaining this.

Relocating effects between A, P and C

Period effect, 0 on average, slope is 0: a regression of β_p on p :

$$g(p) = \tilde{\beta}_p = \beta_p - \hat{\mu}_p - \hat{\delta}_p p$$

Cohort effect, absorbing all time-trend ($\delta_p p = \delta_p(a + c)$) and risk relative to c_0 :

$$h(c) = \gamma_c - \gamma_{c_0} + \hat{\delta}_p(c - c_0)$$

The rest is the age-effect:

$$f(a) = \alpha_a + \hat{\mu}_p + \hat{\delta}_p a + \hat{\delta}_p c_0 + \gamma_{c_0}$$

How it all adds up:

$$\begin{aligned}\lambda(a, p) &= \hat{\alpha}_a + \hat{\beta}_p + \hat{\gamma}_c \\ &= \hat{\alpha}_a + \gamma_{c_0} + \hat{\mu}_p + \hat{\delta}_p(a + c_0) + \\ &\quad \hat{\beta}_p - \hat{\mu}_p - \hat{\delta}_p(a + c) + \\ &\quad \hat{\gamma}_c - \gamma_{c_0} + \hat{\delta}_p(c - c_0)\end{aligned}$$

Only the regression on period is needed! (For this model...)

```
> plot( tc.acp )
```

```
cp.offset  RR.fac  
Age-Period-Cohort model (APC-cat) 1835 1
```

Customize the frame for nicer plot of parameter estimates:

```
> par( mar=c(3,4,0.1,4), mgp=c(3,1,0)/1.6, las=1 )
> apc.frame( a.lab=c(2,4,6)*10,
+           a.tic=1:6*10,
+           cp.lab=1900+0:4*20,
+           cp.tic=1890+0:10*10,
+           r.lab=c(c(1,2,5),c(1,2)*10),
+           r.tic=c(1:10,15,20,25),
+           rr.ref=5 )
> matshade( tc.acp$Age[,1], tc.acp$Age[,-1], lwd=2 )
> pc.matshade( tc.acp$Per[,1], tc.acp$Per[,-1], lwd=2 )
> pc.matshade( tc.acp$Coh[,1], tc.acp$Coh[,-1], lwd=2 )
> pc.points( 1943, 1, pch=16 )
```

A simple practical approach

- ▶ First fit the age-cohort model, with cohort c_0 as reference and get estimates $\hat{\alpha}_a$ and $\hat{\gamma}_c$:

$$\log[\lambda(a, p)] = \hat{\alpha}_a + \hat{\gamma}_c$$

- ▶ Then consider the full APC-model with age and cohort effects constrained to be as estimated from the AC-model:

$$\log[\lambda(a, p)] = \hat{\alpha}_a + \hat{\gamma}_c + \beta_p$$

- ▶ The residual period effect can be estimated if we note that for the number of cases we have:

$$\log(\text{expected cases}) = \log[\hat{\lambda}(a, p) Y] = \underbrace{\hat{\alpha}_a + \hat{\gamma}_c + \log(Y)}_{\text{"known"}} + \beta_p$$

- ▶ This is analogous to the expression for a Poisson model in general,
- ▶ ... but now is the offset not just $\log(Y)$ but $\hat{\alpha}_a + \hat{\gamma}_c + \log(Y)$, the log of the fitted values from the age-cohort model.
- ▶ β_p s are estimated in a Poisson model with this as offset.
- ▶ Advantage: We get the standard errors for free.

Customize the frame for nicer plot of parameter estimates:

```
> par( mar=c(3,4,0.1,4), mgp=c(3,1,0)/1.6, las=1 )
> apc.frame( a.lab=c(2,4,6)*10,
+           a.tic=1:6*10,
+           cp.lab=1900+0:4*20,
+           cp.tic=1890+0:10*10,
+           r.lab=c(c(1,2,5),c(1,2)*10),
+           r.tic=c(1:10,15,20,25),
+           rr.ref=5 )
> matshade( tc.acp$Age[,1], tc.acp$Age[,-1], lwd=2, alpha=0.2 )
> pc.matshade( tc.acp$Per[,1], tc.acp$Per[,-1], lwd=2, alpha=0.2 )
> pc.matshade( tc.acp$Coh[,1], tc.acp$Coh[,-1], lwd=2, alpha=0.2 )
> pc.points( 1943, 1, pch=16 )
> #
> # The stepwise conditioning:
> tc.ac.p <- apc.fit( tc, model="factor", parm="AC-P", ref.c=1943, scale=10^5 )
```

Age at entry Age-Duration-Diagnosis

Bendix Carstensen

Statistical Analysis in the
Lexis Diagram:

Age-Period-Cohort models
— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

Age-at-entry

Age at entry (diagnosis) as covariate

t : time since entry (duration)

e : age at entry

$a = e + t$: current age (age at follow-up)

Duration as basic time-scale; linear effect of age at entry:

$$\log(\lambda(a, t)) = f(t) + \beta e = (f(t) - \beta t) + \beta a$$

Immaterial whether a or e is used as (log)-**linear** covariate as long as t is in the model.

Non-linear effects of time-scales

Arbitrary effects of the three variables t , a and e :
 \Rightarrow genuine extension of the model.

$$\log(\lambda(a, t)) = f(t) + g(a) + h(e)$$

Three quantities can be arbitrarily moved between the three functions:

$$\tilde{f}(t) = f(a) - \mu_a - \mu_e + \gamma t$$

$$\tilde{g}(a) = g(p) + \mu_a - \gamma a$$

$$\tilde{h}(e) = h(c) + \mu_a + \gamma e$$

because $t - a + e = 0$.

This is the age-period-cohort modeling problem again.

“Controlling for age”

— is not a well defined statement:

- ▶ Mostly it means that age **at entry** is included in the model.
- ▶ But ideally one would check whether there were non-linear effects of age at entry and current age.
- ▶ This would require modeling of multiple timescales.
- ▶ Which is best accomplished by splitting follow up and using Poisson models, with time scales as covariates.

Tabulation of register data

Testis cancer cases in Denmark.

Male person-years in Denmark.

Subdivision by year of birth (cohort).

Major sets in the Lexis diagram

A-sets: Classification by age and period. ()

B-sets: Classification by age and cohort. ()

C-sets: Classification by cohort and period. ()

The mean age, period and cohort for these sets is just the mean of the tabulation interval.

The mean of the third variable is found by using $a = p - c$.

Analysis of rates from a complete observation in a Lexis diagram need not be restricted to these classical sets classified by two factors.

We may classify cases and risk time by all three factors

Lexis triangles:

Upper triangles: Classification by age and period, earliest born cohort. (∇)

Lower triangles: Classification by age and period, latest born cohort. (\triangleleft)

Mean a , p and c during FU in triangles

Modeling requires that each set (=observation in the dataset) be assigned a value of age, period and cohort. So for each triangle we need:

- ▶ mean age at risk.
- ▶ mean date at risk.
- ▶ mean cohort at risk.

Means in upper (A) and lower (B) triangles:

Upper triangles (∇), \mathbf{A} :

$$E_{\mathbf{A}}(a) = \int_{p=0}^{p=1} \int_{a=p}^{a=1} a \times 2 \, da \, dp = \int_{p=0}^{p=1} 1 - p^2 \, dp = \frac{2}{3}$$

$$E_{\mathbf{A}}(p) = \int_{a=0}^{a=1} \int_{p=0}^{p=a} p \times 2 \, dp \, da = \int_{a=0}^{a=1} a^2 \, dp = \frac{1}{3}$$

$$E_{\mathbf{A}}(c) = \frac{1}{3} - \frac{2}{3} = -\frac{1}{3}$$

Lower triangles (\triangle), \mathbf{B} :

$$E_{\mathbf{B}}(a) = \int_{p=0}^{p=1} \int_{a=0}^{a=p} a \times 2 \, da \, dp = \int_{p=0}^{p=1} p^2 \, dp = \frac{1}{3}$$

$$E_{\mathbf{B}}(p) = \int_{a=0}^{a=1} \int_{p=a}^{p=1} p \times 2 \, dp \, da = \int_{a=0}^{a=1} 1 - a^2 \, dp = \frac{2}{3}$$

$$E_{\mathbf{B}}(c) = \frac{2}{3} - \frac{1}{3} = \frac{1}{3}$$

Tabulation by age, period and cohort

Gives triangular sets with differing mean age, period and cohort:

These correct midpoints for age, period and cohort must be used in modeling.

From population figures to risk time

Population figures in the form of size of the population at certain date are available from most statistical bureaus.

This corresponds to population sizes along the vertical lines in the diagram.

We want risk time figures for the population in the squares and triangles in the diagram.

Prevalent population figures

$\ell_{a,p}$ is the number of persons in age class a alive at the beginning of period (=year) p .

The aim is to compute person-years for the triangles **A** and **B**, respectively.

The area of the triangle is $1/2$, so the uniform measure over the triangle has density 2. Therefore a person dying in age a at date p in \mathbf{A} contributes p risk time in \mathbf{A} , so the average will be:

$$\begin{aligned} & \int_{p=0}^{p=1} \int_{a=p}^{a=1} 2p \, da \, dp \\ &= \int_{p=0}^{p=1} 2p - 2p^2 \, dp \\ &= \left[p^2 - \frac{2p^3}{3} \right]_{p=0}^{p=1} = \frac{1}{3} \end{aligned}$$

A person dying in age a at date p in **B** contributes $p - a$ risk time in **A**, so the average will be (again using the density 2 of the uniform measure):

$$\begin{aligned} & \int_{p=0}^{p=1} \int_{a=0}^{a=p} 2(p - a) \, da \, dp \\ &= \int_{p=0}^{p=1} [2pa - a^2]_{a=0}^{a=p} \, dp \\ &= \int_{p=0}^{p=1} p^2 \, dp = \frac{1}{3} \end{aligned}$$

A person dying in age a at date p in **B** contributes a risk time in **B**, so the average will be:

$$\int_{p=0}^{p=1} \int_{a=0}^{a=p} 2a \, da \, dp$$

$$= \int_{p=0}^{p=1} p^2 \, dp = \frac{1}{3}$$

Mean contributions to risk time in **A** and **B**:

	A:	B:
Survivors:	$l_{a+1,p+1} \times \frac{1}{2}y$	$l_{a+1,p+1} \times \frac{1}{2}y$
Dead in A :	$\frac{1}{2}(l_{a,p} - l_{a+1,p+1}) \times \frac{1}{3}y$	
Dead in B :	$\frac{1}{2}(l_{a,p} - l_{a+1,p+1}) \times \frac{1}{3}y$	$\frac{1}{2}(l_{a,p} - l_{a+1,p+1}) \times \frac{1}{3}y$
Σ	$(\frac{1}{3}l_{a,p} + \frac{1}{6}l_{a+1,p+1}) \times 1y$	$(\frac{1}{6}l_{a,p} + \frac{1}{3}l_{a+1,p+1}) \times 1y$

The number of deaths in **A** and **B** is $l_{a,p} - l_{a+1,p+1}$, and we assume that half occur in **A** and half in **B**.

Population as of 1. January from Statistics Denmark:

	Men			Women		
	2000	2001	2002	2000	2001	2002
Age						
22	33435	33540	32272	32637	32802	31709
23	35357	33579	33742	34163	32853	33156
24	38199	35400	33674	37803	34353	33070
25	37958	38257	35499	37318	37955	34526
26	38194	38048	38341	37292	37371	38119
27	39891	38221	38082	39273	37403	37525

Exercise:

Fill in the risk time figures in as many triangles as possible from the previous table for men and women, respectively.

Look at the N2Y function in Epi.

Summary:

Population
risk time:

$$\mathbf{A:} \left(\frac{1}{3}l_{a,p} + \frac{1}{6}l_{a+1,p+1} \right) \times 1y$$

$$\mathbf{B:} \left(\frac{1}{6}l_{a-1,p} + \frac{1}{3}l_{a,p+1} \right) \times 1y$$

Mean age, period and
cohort:

$\frac{1}{3}$ into the interval.

APC-model for triangular data

Bendix Carstensen

Statistical Analysis in the
Lexis Diagram:

Age-Period-Cohort models

— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

APC-tri

Model for triangular data

- ▶ One parameter per distinct value on each timescale.
- ▶ Example: 3 age-classes and 3 periods:
 - ▶ 6 age parameters
 - ▶ 6 period parameters
 - ▶ 10 cohort parameters
- ▶ Model:

$$\lambda_{ap} = \alpha_a + \beta_p + \gamma_c$$

Problem: Disconnected design!

Log-likelihood contribution from one triangle:

$$D_{ap} \log(\lambda_{ap}) - \lambda_{ap} Y_{ap} = D_{ap} \log(\alpha_a + \beta_p + \gamma_c) - (\alpha_a + \beta_p + \gamma_c) Y_{ap}$$

The log-likelihood can be separated:

$$\sum_{a,p \in \nabla} D_{ap} \log(\lambda_{ap}) - \lambda_{ap} Y_{ap} + \sum_{a,p \in \triangle} D_{ap} \log(\lambda_{ap}) - \lambda_{ap} Y_{ap}$$

No common parameters between terms

— we have two separate models:

One for upper triangles, one for lower.

Illustration by lung cancer data

```
> library( Epi )
> data( lungDK )
> lungDK[1:10,]
   A5  P5  C5 up      Ax      Px      Cx  D      Y
1  40 1943 1898  1 43.33333 1944.667 1901.333 52 336233.8
2  40 1943 1903  0 41.66667 1946.333 1904.667 28 357812.7
3  40 1948 1903  1 43.33333 1949.667 1906.333 51 363783.7
4  40 1948 1908  0 41.66667 1951.333 1909.667 30 390985.8
5  40 1953 1908  1 43.33333 1954.667 1911.333 50 391925.3
6  40 1953 1913  0 41.66667 1956.333 1914.667 23 377515.3
7  40 1958 1913  1 43.33333 1959.667 1916.333 56 365575.5
8  40 1958 1918  0 41.66667 1961.333 1919.667 43 383689.0
9  40 1963 1918  1 43.33333 1964.667 1921.333 44 385878.5
10 40 1963 1923  0 41.66667 1966.333 1924.667 38 371361.5
```

Fill in the number of cases (D) and person-years (Y) from previous slide.

Indicate birth cohorts on the axes for upper and lower triangles.

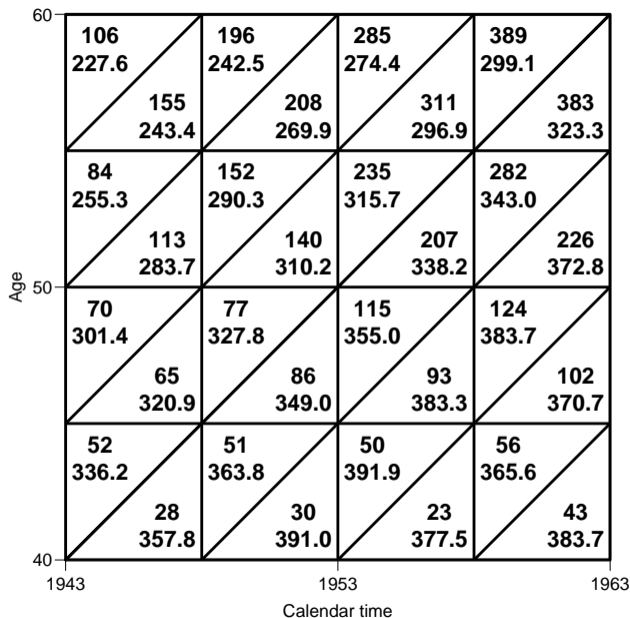

Mark mean date of birth for these.

Fill in the number of cases (D) and person-years (Y) from previous slide.

Indicate birth cohorts on the axes for upper and lower triangles.

Mark mean date of birth for these.

APC-model with “synthetic” cohorts

```
> mc <- glm( D ~ factor(A5) - 1 +  
+           factor(P5-A5) +  
+           factor(P5) + offset( log( Y ) ),  
+           family=poisson )  
> summary( mc )
```

...

```
Null deviance: 1.0037e+08 on 220 degrees of freedom  
Residual deviance: 8.8866e+02 on 182 degrees of freedom
```

No. parameters: $220 - 182 = 38$.

$$A = 10, \quad P = 11, \quad C = 20 \quad \Rightarrow \quad A + P + C - 3 = 38$$

APC-model with “correct” cohorts

```
> mx <- glm( D ~ factor(Ax) - 1 +  
+           factor(Cx) +  
+           factor(Px) + offset( log( Y ) ),  
+           family=poisson )  
> summary( mx )  
...  
Null deviance: 1.0037e+08 on 220 degrees of freedom  
Residual deviance: 2.8473e+02 on 144 degrees of freedom
```

No. parameters: $220 - 144 = 76$ ($= 38 \times 2$).

$$A = 20, \quad P = 22, \quad C = 40 \quad \Rightarrow \quad A + P + C - 3 = 79 \neq 76!$$

We have fitted two age-period-cohort models separately to upper and lower triangles.

Now, explicitly fit models for upper and lower triangles:

```
> mx.u <- glm( D ~ factor(Ax) - 1 +
+             factor(Cx) +
+             factor(Px) + offset( log( Y/10^5 ) ), family=poisson,
+             data=lungDK[lungDK$up==1,] )
> mx.l <- glm( D ~ factor(Ax) - 1 +
+             factor(Cx) +
+             factor(Px) + offset( log( Y/10^5 ) ), family=poisson,
+             data=lungDK[lungDK$up==0,] )
> mx$deviance
[1] 284.7269
> mx.l$deviance
[1] 134.4566
> mx.u$deviance
[1] 150.2703
> mx.l$deviance+mx.u$deviance
[1] 284.7269
```

Modeling for Lexis triangles

- ▶ Modeling by factors not possible
- ▶ Two separate models that cannot be fitted together
- ▶ We are not using the **quantitative** values of age, period and cohort.
- ▶ **Solution:** parametric models using the quantitative nature of a , p and $c = p - a$.
- ▶ ...so we need to handle smooth parametric functions.

Non-linear effects

+           col="black" )
> abline( h=1, v=1970 )
```

Age and period effect

Age and period effect with `ci.exp`

- ▶ In rate models there is always one term with the **rate** dimension.
Usually **age**
- ▶ But it must refer to specific **reference** values for **all other** variables (in this case only P).
- ▶ For the “other” variables, report the RR **relative** to the reference point.
- ▶ Only parameters relevant for the variable (P) actually used in the calculation.
- ▶ We are computing the difference between two predictions.
- ▶ ... as well as the confidence intervals for it.

APC-model: Parametrization

Lexis Diagram:

Age-Period-Cohort models

— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

APC-par

What's the problem?

- ▶ One parameter is assigned to each distinct value of the timescales, the **scale** of the variables is not used.
- ▶ The solution is to “tie together” the points on the scales together with smooth functions of the **mean** age, period and cohort with three functions:

$$\lambda_{ap} = f(a) + g(p) + h(c)$$

- ▶ The practical problem is how to choose a reasonable parametrization of these functions, and how to get estimates.

The identifiability problem still exists:

$$c = p - a \quad \Leftrightarrow \quad p - a - c = 0$$

$$\begin{aligned}\lambda_{ap} &= f(a) + g(p) + h(c) \\ &= f(a) + g(p) + h(c) + \gamma(p - a - c) \\ &= f(a) - \mu_a \quad - \gamma a + \\ &\quad g(p) + \mu_a + \mu_c + \gamma p + \\ &\quad h(c) \quad - \mu_c - \gamma c\end{aligned}$$

A decision on parametrization is needed.
... it must be **external to the model**.

Smooth functions

$$\log(\lambda(a, p)) = f(a) + g(p) + h(c)$$

Possible choices for non-linear parametric functions describing the effect of the three **quantitative** variables:

- ▶ Polynomials / fractional polynomials.
- ▶ Linear / quadratic / cubic splines.
- ▶ Natural splines.

All of these contain the linear effect as special case.

Parametrization of effects

There are still three “free” parameters:

$$\begin{aligned}\tilde{f}(a) &= f(a) - \mu_a - \gamma a \\ \tilde{g}(p) &= g(p) + \mu_a + \mu_c + \gamma p \\ \tilde{h}(c) &= h(c) - \mu_c - \gamma c\end{aligned}$$

Any set of 3 numbers, μ_a , μ_c and γ will produce effects with the same sum:

$$\tilde{f}(a) + \tilde{g}(p) + \tilde{h}(c) = f(a) + g(p) + h(c)$$

The problem is to choose μ_a , μ_c and γ according to some criterion for the functions.

Parametrization principle

1. The age-function should be interpretable as log age-specific rates in a cohort c_0 after adjustment for the period effect.
2. The cohort function is 0 at a reference cohort c_0 , interpretable as log-RR relative to cohort c_0 .
3. The period function is 0 on average with 0 slope, interpretable as log-RR relative to the age-cohort prediction. (residual log-RR).

This will yield cohort age-effects a.k.a. **longitudinal** age effects.

Biologically interpretable:

— what happens during the lifespan of a cohort?

Period-major parametrization

- ▶ Alternatively, the period function could be constrained to be 0 at a reference date, p_0 .
- ▶ Then, age-effects at $a_0 = p_0 - c_0$ would equal the fitted rate for period p_0 (and cohort c_0), and the period effects would be residual log-RRs relative to p_0 .
- ▶ Gives period or **cross-sectional** age-effects
- ▶ Bureaucratically interpretable:
 - what was seen at a particular date?

Implementation:

1. Obtain any set of parameters $f(a)$, $g(p)$, $h(c)$.
2. Extract the trend from the period effect (find μ and β):

$$\tilde{g}(p) = \hat{g}(p) - (\mu + \beta p)$$

3. Decide on a reference cohort c_0 .
4. Use the functions:

$$\tilde{f}(a) = \hat{f}(a) + \mu + \beta a + \hat{h}(c_0) + \beta c_0$$

$$\tilde{g}(p) = \hat{g}(p) - \mu - \beta p$$

$$\tilde{h}(c) = \hat{h}(c) + \beta c - \hat{h}(c_0) - \beta c_0$$

“Extract the trend”

- ▶ **Not** a well-defined concept:
 - ▶ Regress $\hat{g}(p)$ on p for all units in the dataset.
 - ▶ Regress $\hat{g}(p)$ on p for all different values of p .
 - ▶ Weighted regression — what weights?
- ▶ How do we get the standard errors?
- ▶ Matrix-algebra!
- ▶ Projections!
- ▶ Weighted inner product. . .

Parametric function

Suppose that $g(p)$ is parametrized using the design matrix \mathbf{M} , with the estimated parameters π .

Example: 2nd degree polynomial:

$$\mathbf{M} = \begin{bmatrix} 1 & p_1 & p_1^2 \\ 1 & p_2 & p_2^2 \\ \vdots & \vdots & \vdots \\ 1 & p_n & p_n^2 \end{bmatrix} \quad \pi = \begin{bmatrix} \pi_0 \\ \pi_1 \\ \pi_2 \end{bmatrix} \quad g(p) = \mathbf{M}\pi$$

$\text{nrow}(\mathbf{M})$ is the no. of observations in the dataset,

$\text{ncol}(\mathbf{M})$ is the no. of parameters

Extract the trend from g :

Vectors \mathbf{x} and \mathbf{y} are orthogonal if the inner product is 0

$$\mathbf{x} \perp \mathbf{y} \quad \Leftrightarrow \quad \langle \mathbf{x} | \mathbf{y} \rangle = \sum_i x_i y_i = 0$$

- ▶ $\langle \tilde{g}(p) | 1 \rangle = 0$, $\langle \tilde{g}(p) | p \rangle = 0$, i.e. \tilde{g} is **orthogonal** to $[1:p]$.
- ▶ Suppose $\tilde{g}(p) = \tilde{\mathbf{M}}\pi$, then for **any** parameter vector π :
$$\langle \tilde{\mathbf{M}}\pi | 1 \rangle = 0, \quad \langle \tilde{\mathbf{M}}\pi | p \rangle = 0 \quad \Longrightarrow \quad \tilde{\mathbf{M}} \perp [1:p]$$
- ▶ Thus we just need to be able to produce $\tilde{\mathbf{M}}$ from \mathbf{M} :
Projection on the orthogonal complement of $\text{span}([1:p])$.
- ▶ **But:** orthogonality requires an inner product!

Practical parametrization

1. Set up model matrices for age, period and cohort, M_a , M_p and M_c . Intercept in all three.
2. Extract the linear trend from M_p and M_c , by projecting their columns onto the orthogonal complement of $[1:p]$ and $[1:c]$, respectively
3. Center the cohort effect around c_0 :
Take a row from \tilde{M}_c corresponding to c_0 , replicate to dimension as \tilde{M}_c , and subtract it from \tilde{M}_c to form \tilde{M}_{c_0} .

4. Use:

M_a for the age-effects,

\tilde{M}_p for the period effects and

$[c - c_0 : \tilde{M}_{c_0}]$ for the cohort effects.

5. Value of $\hat{f}(a)$ is $M_a \hat{\beta}_a$, similarly for the other two effects.

Variance is found by $M'_a \hat{\Sigma}_a M_a$, where $\hat{\Sigma}_a$ is the variance-covariance matrix of $\hat{\beta}_a$.

Information about a parameter in the data

Information about log-rate $\theta = \log(\lambda)$:

$$l(\theta|D, Y) = D\theta - e^\theta Y, \quad l'_\theta = D - e^\theta Y, \quad l''_\theta = -e^\theta Y$$

so $I(\hat{\theta}) = e^{\hat{\theta}} Y = \hat{\lambda} Y = D$.

Information about square root of rate $\sigma = \sqrt{\lambda}$:

$$l(\sigma|D, Y) = D\log(\sigma^2) - \sigma^2 Y, \quad l'_\sigma = (D/\sigma^2)2\sigma - 2\sigma Y = 2D/\sigma - 2\sigma Y$$
$$l''_\sigma = -2D/\sigma^2 - 2Y$$

so $I(\hat{\sigma}) = -2D/\hat{\sigma}^2 - 2Y = -4Y$

Information in the data and inner product

- ▶ Inner products:

$$\langle \mathbf{m}_j | \mathbf{m}_k \rangle = \sum_i m_{ij} m_{ik} \quad \langle \mathbf{m}_j | \mathbf{m}_k \rangle = \sum_i m_{ij} w_i m_{ik}$$

- ▶ Weights could be chosen as:

- ▶ $w_i = Y_i$, *i.e.* proportional to the information content for $\sigma = \sqrt{\lambda}$,
dr.extr = Y (the default)
- ▶ $w_i = D_i$, *i.e.* proportional to the information content for $\theta = \log(\lambda)$,
dr.extr $\in c(D, T)$
- ▶ $w_i = Y_i^2 / D_i$, *i.e.* proportional to the information content for λ ,
dr.extr $\in c(L, R)$
- ▶ $w_i = 1$, the “usual” inner product — implicitly used in most of the literature — any other (character) value for dr.extr.

How to? I

Implemented in `apc.fit` in the `Epi` package:

```
> library( Epi )  
> library( splines )  
> data( lungDK )
```

```
> mw <- apc.fit( A = lungDK$Ax,  
+               P = lungDK$Px,  
+               D = lungDK$D,  
+               Y = lungDK$Y/1000,  
+               ref.c = 1900,  
+               npar = 8,  
+               parm = "ACP",  
+               dr.extr = "y", print.AOV=FALSE ) # drift extraction - choice of inner p
```

Substantial differences between the estimated drifts.

Parametrization of the APC model is arbitrary

- ▶ Separation of the three effects relies on arbitrary principles, e.g.:
 - ▶ Age is the primary effect
 - ▶ Cohort the secondary, reference c_0
 - ▶ Period is the residual
 - ▶ Inner product for trend extraction
- ▶ There is no magical fix that allows you to escape this, it comes from modelling a , p and $p - a$
- ▶ Any fix has some (hidden) assumption(s)
- ▶ ... but the **fitted values** are the same

Lexis Diagram:

Age-Period-Cohort models

— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

LeeCarter

Lee-Carter model for (mortality) rates

Lee & Carter, JASA, 1992:

$$\log(\lambda_{x,t}) = a_x + b_x \times k_t$$

x is age; t is calendar time

- ▶ Formulated originally using as step-functions with one parameter per age/period.
- ▶ Implicitly assumes a data lay out by age and period: A, B or C-sets, but **not** Lexis triangles
- ▶ Using Lexis triangles with categorical set-up would just produce separate models for upper and lower triangles.

Lee-Carter model in continuous time

For **any** set of subsets of a Lexis diagram:

$$\log(\lambda(a, t)) = f(a) + b(a) \times k(t)$$

- ▶ $f(a)$, $b(a)$ smooth functions of age, a is **quantitative**
- ▶ $k(t)$ smooth function of period, t is **quantitative**
- ▶ Relative **scaling** of $b(a)$ and $k(t)$ cannot be determined
- ▶ $k(t)$ only determined up to an **affine** transformation:

$$\begin{aligned} f(a) + b(a)k(t) &= f(a) + (b(a)/n)(m + k(t) \times n) \\ &\quad - (b(a)/n) \times m \\ &= \tilde{f}(a) + \tilde{b}(a)\tilde{k}(t) \end{aligned}$$

Lee-Carter model in continuous time

$$\log(\lambda(a, t)) = f(a) + b(a) \times k(t)$$

- ▶ Lee-Carter model is an extension of the age-period model; if $b(a) = 1$ it **is** the age-period model.
- ▶ The extension is an age \times period interaction, but not a traditional one:

$$\log(\lambda(a, t)) = f(a) + b(a) \times k(t) = f(a) + k(t) + (b(a) - 1) \times k(t)$$

- ▶ Main effect and interaction component of t are constrained to be identical.

Main effect and interaction term

Main effect and interaction component of t are constrained to be identical.

None of these are Lee-Carter models:

```
> glm( D ~ Ns(A, kn=a1.kn) + Ns(A, kn=a2.kn, i=T) : Ns(P, kn=p.kn), ... )  
> glm( D ~ Ns(A, kn=a1.kn) + Ns(A, kn=a2.kn, i=T) * Ns(P, kn=p.kn), ... )  
> glm( D ~ Ns(A, kn=a1.kn) + Ns(P, kn=p.kn) + Ns(A, kn=a2.kn, i=T) : Ns(P, kn=p.kn), ... )
```

Lee-Carter model interpretation

$$\log(\lambda(a, p)) = f(a) + b(a) \times k(p)$$

- ▶ Constraints:
- ▶ $f(a)$ is the basic age-specific mortality
- ▶ $k(p)$ is the rate-ratio (RR) as a function of p :
 - ▶ relative to a p_{ref} where $k(p_{\text{ref}}) = 1$
 - ▶ for persons aged a_{ref} where $b(a_{\text{ref}}) = 1$
- ▶ $b(a)$ is an age-specific multiplier for the RR $k(p)$
- ▶ Choose p_{ref} and a_{ref} *a priori*.

Danish lung cancer data I

```
> lung <- read.table( "../data/apc-Lung.txt", header=T )  
> head( lung )
```

```
  sex A    P    C D      Y

3   1 0 1944 1943 0 20681.3  
4   1 0 1944 1944 0 22478.5  
5   1 0 1945 1944 0 22369.2  
6   1 0 1945 1945 0 23885.0
```

```
> # Only A by P classification - and only men over 40  
> ltab <- xtabs( cbind(D,Y) ~ A + P, data=subset(lung,sex==1) )  
> str( ltab )
```

Danish lung cancer data II

```
xtabs [1:90, 1:61, 1:2] 0 0 0 0 0 0 0 0 0 0 0 ...  
- attr(*, "dimnames")=List of 3  
..$ A: chr [1:90] "0" "1" "2" "3" ...  
..$ P: chr [1:61] "1943" "1944" "1945" "1946" ...  
..$ : chr [1:2] "D" "Y"  
- attr(*, "call")= language xtabs(formula = cbind(D, Y) ~ A + P, data = subset(lu
```

Lee-Carter modeling in **R**-packages:

- ▶ demography (`lca`)
- ▶ ilc (`lca.rh`)
- ▶ Epi (`LCa.fit`).

Lee-Carter with demography I

```
> library(demography)
> lcM <- demogdata( data = as.matrix(ltab[40:90,, "D"]/ltab[40:90,, "Y"]),
+                 pop = as.matrix(ltab[40:90,, "Y"]),
+                 ages = as.numeric(dimnames(ltab)[[1]][40:90]),
+                 years = as.numeric(dimnames(ltab)[[2]]),
+                 type = "Lung cancer incidence",
+                 label = "Denmark",
+                 name = "Male" )
```

`lca` estimation function checks the `type` argument, so we make a work-around, `mrt`:

Lee-Carter with demography II

```
> mrt <- function(x) { x$type <- "mortality" ; x }
> dmg.lcM <- lca( mrt(lcM), interpolate=TRUE )
> par( mfcol=c(1,3) )
> matplot( dmg.lcM$age, exp(dmg.lcM$ax)*1000,
+         log="y", ylab="Lung cancer incidence rates per 1000 PY",
+         xlab="Age", type="l", lty=1, lwd=4 )
> matplot( dmg.lcM$age, dmg.lcM$bx,
+         ylab="Age effect",
+         xlab="Age", type="l", lty=1, lwd=4 )
> matplot( dmg.lcM$year, dmg.lcM$kt,
+         ylab="Time effect",
+         xlab="Date", type="l", lty=1, lwd=4 )
> abline(h=0)
```

Lee-Carter with demography

Lee-Carter re-scaled I

$$\log(\hat{\lambda}(a, p)) = [f(a) + b(a) \times 20] + [b(a) \times 50] \times [(k(t) - 20)/50]$$

```
> par( mfcol=c(1,3) )
> matplot( dmg.lcM$age, exp(dmg.lcM$ax+dmg.lcM$bx*20)*1000,
+         log="y", ylab="Lung cancer incidence rates per 1000 PY",
+         xlab="Age", type="l", lty=1, lwd=4 )
> matplot( dmg.lcM$age, dmg.lcM$bx*50,
+         ylab="Age effect",
+         xlab="Age", type="l", lty=1, lwd=4 )
> abline(h=1)
> matplot( dmg.lcM$year, (dmg.lcM$kt-20)/50,
+         ylab="Time effect",
+         xlab="Date", type="l", lty=1, lwd=4 )
> abline(h=0)
```

Lee-Carter with demography rescaled

Lee-Carter with `ilc`

- ▶ The `lca.rh` function fits the model using maximum likelihood (proportional scaling)
- ▶ Fits the more general model and submodels of it:

$$\log(\lambda(a, p)) = f(a) + b(a) \times k(p) + c(a)m(p - a)$$

- ▶ Age interaction with between age and both period and/or cohort (=period-age)
 - ▶ It is also an extension of the APC-model; if $b(a) = 1$ and $c(a) = 1$ it's the APC-model.
- ⇒ suffers from the same identifiability problem

Lee-Carter with `ilc` I

```
> library( ilc )  
> ilc.lcM <- lca.rh( mrt(lcM), model="lc", interpolate=TRUE, verbose=FALSE )
```

Original sample: Mortality data for Denmark

Series: Male

Years: 1943 - 2003

Ages: 39 - 89

Applied sample: Mortality data for Denmark (Corrected: interpolate)

Series: Male

Years: 1943 - 2003

Ages: 39 - 89

Fitting model: [$LC = a(x) + b1(x) * k(t)$]

- with poisson error structure and with deaths as weights -

Iterations finished in: 34 steps

```
> plot( ilc.lcM )
```

Lee-Carter with `ilc`

Age-Period LC Regression for Denmark [Male]

Lee-Carter with Epi

- ▶ `LCa.fit` fits the Lee-Carter model using natural splines for the **quantitative** effects of age and time.
- ▶ Normalizes effects to a reference age and period.
- ▶ The algorithm alternately fits a main age and period effects and the age-interaction effect.

$$\log(\lambda(a, p)) = f(a) + b(a) \times k(p) + c(a) \times m(p - a)$$

$$\log(\lambda(a, p)) = f(a) + b(a) \times k(p) + c(a) \times m(p - a)$$

Lee-Carter with Epi I

```
> library( Epi )  
> Mlc <- subset( lung, sex==1 & A>39 )  
> LCa.Mlc <- LCa.fit( Mlc, a.ref=60, p.ref=1980 )
```

LCa.fit convergence in 8 iterations, deviance: 8548.443 on 6084 d.f.

```
> LCa.Mlc
```

APa: Lee-Carter model with natural splines:
log(Rate) = ax(Age) + pi(Age)kp(Per)
with 6, 5 and 5 parameters respectively.
Deviance: 8548.443 on 6084 d.f.

```
> plot( LCa.Mlc, rnam="Lung cancer incidence per 1000 PY" )
```

Lee-Carter with Epi

Lee-Carter and the APC-model

- ▶ Lee-Carter model is an interaction extension of the Age-Period model
- ▶ ... or an interaction extension of the Age-Cohort model
- ▶ Age-Period-Cohort model is:
 - ▶ interaction extension
 - ▶ the smallest **union** of Age-Period and Age-Cohort
- ▶ Extended Lee-Carter (from the `ilc` package)

$$\log(\lambda(a, p)) = f(a) + b(a) \times k(p) + c(a)m(p - a)$$

is the union of all of these.

Lee-Carter and the APC-model

```
> system.time( allmod <- apc.LCa( M1c, keep.models=TRUE ) )  
> str( allmod )  
> save( allmod, file='allmod.Rda' )
```

```
> load( file='allmod.Rda' )  
> show.apc.LCa( allmod, top="Ad" )
```

```
> show.apc.LCa( allmod, top="AP" )
```

```
> show.apc.LCa( allmod, top="AC" )
```

Lee-Carter models and APC models

Lee-Carter models and APC models

- ▶ The classical Lee-Carter model is an extension of the Age-Period model with an interaction
- ▶ The Age-Period-Cohort model is an extension of the Age-Period model with an interaction
- ▶ Replacing period with cohort gives another type of Lee-Carter model
- ▶ The logical step is to consider all 9 models that comes from cross-classification of how the interaction term $b(a)$
 - ▶ Linear effect ($b(a) = 0$)
 - ▶ Non-linear effect ($b(a) = 1$)
 - ▶ Multiplicative interaction with age ($b(a)$ unconstrained)

Lee-Carter models and APC models

		$b_c(a)$		
		0	1	free
$b_p(a)$	0	Age	Age+Coh	LCa(C) <i>AC, ac, ACa</i>
	1	Age+Per	Age+Per+Coh <i>H₀, h0</i>	Age+Per+LCa(C) <i>H₁, h1, APCa</i>
	free	LCa(P) <i>LC, lc, APa</i>	Age+Coh+LCa(P) <i>H₂, h2, APaC</i>	Age+LCa(P)+LCa(C) <i>M, m, APaCa</i>

Model: `ilc: lca.rh(model=)` `Epi: LCa.fit(model=)`

APC-models for several datasets

Lexis Diagram:

Age-Period-Cohort models

— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

Two APC-models

- ▶ APC-models for two sets of rates (men/women, say)

$$\log(\lambda_i(a, p)) = f_i(a) + g_i(p) + h_i(p - a), \quad i = 1, 2$$

- ▶ Rate-ratio also an APC-model:

$$\begin{aligned} \log(\text{RR}(a, p)) &= \log(\lambda_1(a, p)) - \log(\lambda_2(a, p)) \\ &= (f_1(a) - f_2(a)) + (g_1(p) - g_2(p)) \\ &\quad + (h_1(p - a) - h_2(p - a)) \\ &= f_{\text{RR}}(a) + g_{\text{RR}}(p) + h_{\text{RR}}(p - a) \end{aligned}$$

- ▶ Model the two sets of rates separately and report the ratio effects as any other APC-model.
- ▶ Note; not all constraints carry over to RR

Two sets of data I

Example: Testis cancer in Denmark, Seminoma and non-Seminoma cases.

```
> th <- read.table( "../data/testis-hist.txt", header=TRUE )  
> str( th )
```

```
'data.frame': 29160 obs. of 9 variables:  
 $ a      : int  0 0 0 0 0 0 1 1 1 1 ...  
 $ p      : int  1943 1943 1943 1943 1943 1943 1943 1943 1943 1943 ...  
 $ c      : int  1942 1942 1942 1943 1943 1943 1941 1941 1941 1942 ...  
 $ y      : num  18853 18853 18853 20796 20796 ...  
 $ age    : num  0.667 0.667 0.667 0.333 0.333 ...

```

```
> ( Pkn <- (apc.Sem$Knots$Per+apc.nS$Knots$Per)/2 )
```

```
[1] 1952.417 1964.000 1972.333 1978.167 1983.000 1987.500 1991.500 1995.000
```

```
> ( Ckn <- (apc.Sem$Knots$Coh+apc.nS$Knots$Coh)/2 )
```

```
[1] 1913.500 1926.000 1934.833 1942.000 1947.833 1953.333 1958.958 1966.000
```

```
> apc.sem <- apc.fit( subset(th,hist=="Sem"), npar=list(A=Akn,P=Pkn,C=Ckn), pr=F )
```

No reference period given:

Reference period for age-effects is chosen as

the median date of birth for persons with event: 1939.667 .

Analysis of two rates: Formal tests II

```
> apc.ns <- apc.fit( subset(th,hist=="nS" ), npar=list(A=Akn,P=Pkn,C=Ckn), pr=F )
```

No reference period given:

Reference period for age-effects is chosen as
the median date of birth for persons with event: 1949.667 .

Joint model, parametrize interactions separately:

Analysis of two rates: Formal tests III

```
> Ma <- with( th, Ns( A, knots=Akn, intercept=TRUE ) )
> Mp <- with( th, Ns( P , knots=Pkn ) )
> Mc <- with( th, Ns( P-A, knots=Ckn ) )
> # extract the linear trend
> Mp <- detrend( Mp, th$P , weight=th$D )
> Mc <- detrend( Mc, th$P-th$A, weight=th$D )
> m.apc <- glm( D ~ -1 + Ma:hist + Mp:hist + Mc:hist +
+             P:hist + # note separate slopes extracted
+                   offset( log(Y)),
+             family=poisson, data=th )
> m.apc$deviance
```

```
[1] 9410.446
```

```
> # Same as the sum from separate models
> apc.ns$Model$deviance + apc.sem$Model$deviance
```

```
[1] 9410.446
```

Analysis of two rates: Formal tests IV

Tests for equality of non-linear part of shapes

```
> m.ap <- update( m.apc, . ~ . - Mc:hist + Mc )
> m.ac <- update( m.apc, . ~ . - Mp:hist + Mp )
> m.a <- update( m.ap , . ~ . - Mp:hist + Mp )
> m.d <- update( m.ap , . ~ . - Mp:hist )
> m.O <- update( m.ap , . ~ . - P:hist + P )
> AOV <- anova( m.a, m.ac, m.apc, m.ap, m.a, m.d, m.O, test="Chisq")
> rownames( AOV ) <- c("", "cohRR", "perRR|coh", "cohRR|per", "perRR", "drift", "Smdrift")
> AOV
```

Analysis of two rates: Formal tests V

Analysis of Deviance Table

```
Model 1: D ~ Mc + Mp + Ma:hist + hist:P + offset(log(Y)) - 1
Model 2: D ~ Mp + Ma:hist + hist:Mc + hist:P + offset(log(Y)) - 1
Model 3: D ~ -1 + Ma:hist + Mp:hist + Mc:hist + P:hist + offset(log(Y))
Model 4: D ~ Mc + Ma:hist + hist:Mp + hist:P + offset(log(Y)) - 1
Model 5: D ~ Mc + Mp + Ma:hist + hist:P + offset(log(Y)) - 1
Model 6: D ~ Mc + Ma:hist + hist:P + offset(log(Y)) - 1
Model 7: D ~ Mc + P + Ma:hist + hist:Mp + offset(log(Y)) - 1
```

perRR	10770	9467.4	-6	-45.783	3.270e-08
drift	10776	9538.2	-6	-70.807	2.793e-13
Smdrift	10765	9425.6	11	112.612	< 2.2e-16

Several datasets I

- ▶ Separate models for each
- ▶ Rate-ratios between two sets of fitted rates also follow an APC model
- ▶ Constraints does not necessarily carry over to RRs
- ▶ Test for equality of effects: non-linear and linear
- ▶ Take care not to violate the **principle of marginality**: — do not test linear terms when non-linear terms are in the model.

```

Analysis of DM-rates: Age×sex interaction I

A bit more intuitive, independent of parametrization:

```
> apcS <- glm( D ~ Ns(A,knots=A.kn,intercept=TRUE):sex +  
+             Ns(P,knots=P.kn) + Ns(C,knots=C.kn) +  
+             offset( log (Y/10^5) ),  
+             family=poisson, epsilon = 1e-10,  
+             data=dm )
```

```
> apcS$deviance
```

```
[1] 633.5838
```

```
> apcs$deviance
```

```
[1] 633.5838
```

Analysis of DM-rates: Age×sex interaction II

```

```

Analysis of DM-rates: Age \times sex interaction IV

- ▶ ... but these are not the estimates we really want as before.
- ▶ The detrended estimates are not available from the fitted values, because the parametrization they rely on is a function of **data**.
- ▶ Of course the parameters can be extracted but it requires a construction of the model matrices as we did first
- ▶ How is shown in the section “Reparametrizations” in the notes on “Introductory linear algebra with R”.

No. parameters for each curve: 4

No. parameters for each curve: 5

Predicting future rates

predict

Prediction of future rates

Model:

$$\log(\lambda(a, p)) = f(a) + g(p) + h(c)$$

- ▶ Why not just extend the estimated functions into the future?
- ▶ Natural splines lend themselves easily to this [?]
- ▶ The parametrization curse — the model as stated is not uniquely parametrized.
- ▶ Predictions from the model must be invariant under reparametrization.

Identifiability

Predictions based in the three functions $(f(a), g(p)$ and $h(c)$ must give the same prediction also for the reparametrized version:

$$\begin{aligned}\log(\lambda(a, p)) &= \tilde{f}(a) + \tilde{g}(p) + \tilde{h}(c) \\ &= (f(a) - \gamma a) + \\ &\quad (g(p) + \gamma p) + \\ &\quad (h(c) - \gamma c)\end{aligned}$$

A prediction based on the parametrization $(f(a), g(p), h(c))$ must give the same predictions as one based on $(\tilde{f}(a), \tilde{g}(p), \tilde{h}(c))$

Parametrization invariance

- ▶ Prediction of the future course of g and h must preserve addition of a linear term in the argument:

$$\begin{aligned}\text{pred}(g(p) + \gamma p) &= \text{pred}(g(p)) + \gamma p \\ \text{pred}(h(c) - \gamma c) &= \text{pred}(h(c)) - \gamma c\end{aligned}$$

- ▶ If this is met, the predictions made will not depend on the parametrization chosen.
- ▶ If one of the conditions does not hold, the prediction will depend on the parametrization chosen.
- ▶ Any linear combination of (known) function values of $g(p)$ and $h(c)$ will work.

Identifiability

- ▶ Any linear combination of function values of $g(p)$ and $h(c)$ will work.
- ▶ Coefficients in the linear combinations used for g and h must be the same; otherwise the prediction will depend on the specific parametrization.
- ▶ What works best in reality is difficult to say: depends on the subject matter.

Example: Breast cancer in Denmark

Practicalities

- ▶ Long term predictions notoriously unstable.
- ▶ Decreasing slopes are possible, the requirement is that at any future point changes in the parametrization should cancel out in the predictions.

Breast cancer prediction

Predicted
age-specific breast
cancer rates at 2020
& 2030,

in the 1960 and
1970 cohorts.

Continuous outcomes

cont

APC-model for quantitative outcomes

- ▶ The classical model is:

$$\log(\lambda(a, p)) = f(a) + g(p) + h(p - a)$$

- ▶ In principle it would be possible to use an identity-link model:

$$\lambda(a, p) = f(a) + g(p) + h(p - a)$$

- ▶ ... or use APC-modelling for **measurement** data such as BMI, measured at different times and ages:

$$\text{BMI}_{ap} = f(a) + g(p) + h(p - a) + e_{ap}, \quad e_i \sim \mathcal{N}(0, \sigma^2)$$

- ▶ ... or more precisely:

$$\text{BMI}_i = f(a(i)) + g(p(i)) + h(p(i) - a(i)) + e_i, \quad e_i \sim \mathcal{N}(0, \sigma^2)$$

APC-model for quantitative outcomes

- ▶ Model:

$$\text{BMI}_i = f(a(i)) + g(p(i)) + h(p(i) - a(i)) + e_i, \quad e_i \sim \mathcal{N}(0, \sigma^2)$$

- ▶ But the identification problem is still the same:

$$c(i) = p(i) - a(i), \quad \forall i$$

- ▶ But the same machinery applies with extraction of the effects
- ▶ — and plotting of predictions of
 - ▶ E(BMI)
 - ▶ quantiles of BMI

APC-model for quantitative outcomes

- ▶ Australian surveys
- ▶ 40,000+ person surveyed at different times
- ▶ Date of birth, data of survey, sex and BMI known.
- ▶ How does BMI evolve **in the population?**
- ▶ Linear model ($E(\text{BMI})$)
- ▶ Quantile regression (median, quantile)
- ▶ — the latter is not a model
