

Statistical Analysis in the Lexis Diagram: Age-Period-Cohort models — and some cousins

Bendix Carstensen Steno Diabetes Center Copenhagen, Gentofte, Denmark
<http://BendixCarstensen.com>

European Doctoral School of Demography, Odense, April 2019

From /home/bendix/teach/APC/EDSD.2019/slides/slides.tex

Monday 1st April, 2019, 13:12

1/ 332

About the lectures

- ▶ Please interrupt:
Most likely I did a mistake or left out a crucial argument.
- ▶ The handouts are not perfect
— please comment on them,
prospective students would benefit from it.
- ▶ Time-schedule:
Two lectures (\approx 2 hrs)
one practical (\approx 1 hr)

Introduction (intro)

4/ 332

Introduction

Bendix Carstensen

Statistical Analysis in the
Lexis Diagram:

Age-Period-Cohort models
— and some cousins
European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

intro

Welcome

- ▶ Purpose of the course:
 - ▶ knowledge about APC-models
 - ▶ technical knowledge of handling them
 - ▶ insight in the basic concepts of analysis of rates
 - ▶ handling observation in the Lexis diagram
- ▶ Remedies of the course:
 - ▶ Lectures with handouts (BxC)
 - ▶ Practicals with suggested solutions (BxC)
 - ▶ Assignment for Thursday

Scope of the course

- ▶ Rates as observed in populations
 - disease registers for example.
- ▶ Understanding of survival analysis (statistical analysis of rates)
 - this is the content of much of the first day.
- ▶ Besides concepts, practical understanding of the actual computations (in R) are emphasized.
- ▶ There is a section in the practicals:
“Basic concepts of rates and survival”
 - read it; use it as reference.
- ▶ If you are not quite familiar with matrix algebra in R, there is an intro on the course homepage.

Introduction (intro)

2/ 332

Rates and Survival

Bendix Carstensen

Statistical Analysis in the
Lexis Diagram:

Age-Period-Cohort models
— and some cousins
European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

surv-rate

Survival data

- ▶ Persons enter the study at some date.
- ▶ Persons exit at a later date, either dead or alive.
- ▶ Observation:
 - ▶ Actual time span to death (“event”)
 - ▶ ... or ...
 - ▶ Some time alive (“at least this long”)

Rates and Survival (surv-rate)

6/ 332

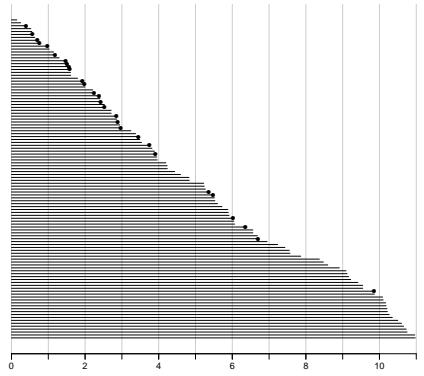

Examples of time-to-event measurements

- Time from diagnosis of cancer to death.
- Time from randomization to death in a cancer clinical trial
- Time from HIV infection to AIDS.
- Time from marriage to 1st child birth.
- Time from marriage to divorce.
- Time from jail release to re-offending

Rates and Survival (surv-rate)

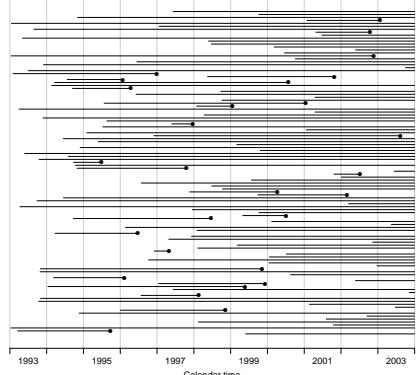

7 / 332

Patients ordered by survival time.

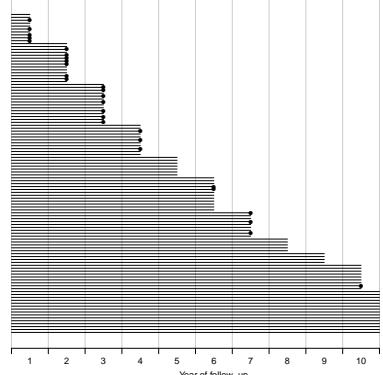

11 / 332

Each line a person

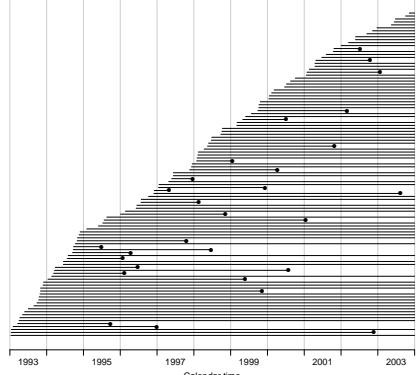

8 / 332

Survival times grouped into bands of survival.

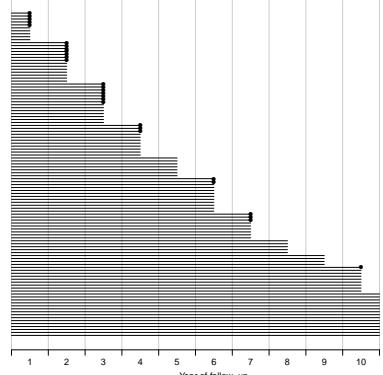

12 / 332

Ordered by date of entry

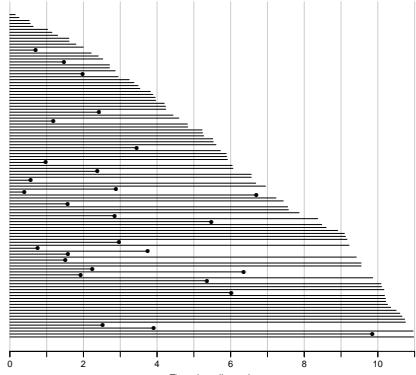

9 / 332

Patients ordered by survival status within each band.

13 / 332

Timescale changed to "Time since diagnosis".

10 / 332

Survival after Cervix cancer

Year	Stage I			Stage II		
	N	D	L	N	D	L
1	110	5	5	234	24	3
2	100	7	7	207	27	11
3	86	7	7	169	31	9
4	72	3	8	129	17	7
5	61	0	7	105	7	13
6	54	2	10	85	6	6
7	42	3	6	73	5	6
8	33	0	5	62	3	10
9	28	0	4	49	2	13
10	24	1	8	34	4	6

Estimated risk in year 1 for Stage I women is $5/107.5 = 0.0465$

Estimated 1 year survival is $1 - 0.0465 = 0.9535$ — Life-table estimator.

Rates and Survival (surv-rate)

14 / 332

Survival function

Persons enter at time 0:
 Date of birth
 Date of randomization
 Date of diagnosis.

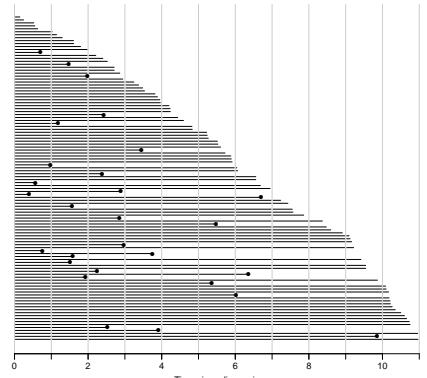

How long they survive, survival time T — a stochastic variable.

Distribution is characterized by the survival function:

$$\begin{aligned} S(t) &= P\{\text{survival at least till } t\} \\ &= P\{T > t\} = 1 - P\{T \leq t\} = 1 - F(t) \end{aligned}$$

Rates and Survival (surv-rate)

15 / 332

19 / 332

Intensity or rate

$$\begin{aligned} \lambda(t) &= P\{\text{event in } (t, t+h] \mid \text{alive at } t\} / h \\ &= \frac{F(t+h) - F(t)}{S(t) \times h} \\ &= -\frac{S(t+h) - S(t)}{S(t)h} \xrightarrow{h \rightarrow 0} -\frac{d \log S(t)}{dt} \end{aligned}$$

This is the **intensity** or **hazard function** for the distribution.

Characterizes the survival distribution as does f or F .

Theoretical counterpart of a **rate**.

Rates and Survival (surv-rate)

16 / 332

20 / 332

Two timescales

Note that we actually have two timescales:

- ▶ Time since diagnosis (*i.e.* since entry into the study)
- ▶ Calendar time.

These can be shown **simultaneously** in a Lexis diagram.

Rates and Survival (surv-rate)

20 / 332

Empirical rates for individuals

- ▶ At the **individual** level we introduce the **empirical rate**: (d, y) ,
 — no. of events ($d \in \{0, 1\}$) during y risk time
- ▶ Each person may contribute several empirical (d, y)
- ▶ Empirical rates are **responses** in survival analysis
- ▶ The timescale is a **covariate**:
 — that varies between empirical rates from one individual:
 Age, calendar time, time since diagnosis
- ▶ Do not confuse timescale with
 y — risk time (called exposure in demography)
 a **difference** between two points on **any** timescale

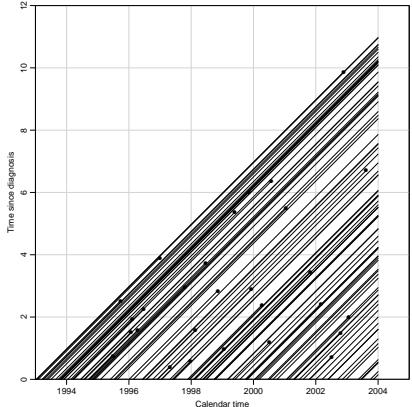

Rates and Survival (surv-rate)

17 / 332

21 / 332

Follow-up by
calendar time *and*
time since diagnosis:

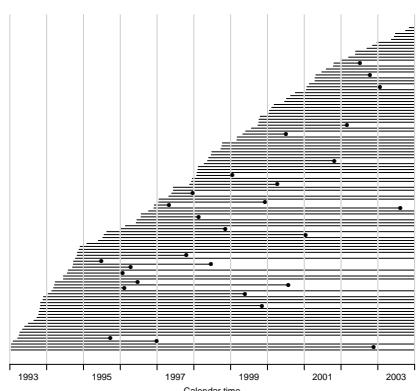

A Lexis
diagram!

Rates and Survival (surv-rate)

21 / 332

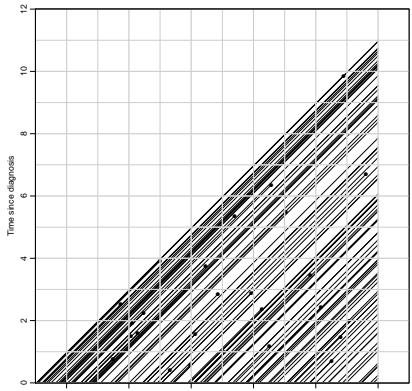

Empirical rates by
calendar time.

Rates and Survival (surv-rate)

18 / 332

Empirical rates by
calendar time *and*
time since diagnosis

Rates and Survival (surv-rate)

22 / 332

So what's the purpose

- form the basis for statistical inference about occurrence rates:
- response: observed rates of events and person-time (d, y)
- covariates:
 - A:** Age at follow-up
 - P:** Period (date) of follow-up
 - C:** (=P-A) Cohort (date of birth)

Rates and Survival (surv-rate)

23 / 332

Likelihood for rates

Bendix Carstensen

Statistical Analysis in the Lexis Diagram:

Age-Period-Cohort models
— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

likelihood

Likelihood contribution from one person

The likelihood from several empirical rates from one individual is a product of conditional probabilities:

$$\begin{aligned} P\{\text{event at } t_4 \mid \text{alive at } t_0\} &= P\{\text{event at } t_4 \mid \text{alive at } t_3\} \times \\ &\quad P\{\text{survive } (t_2, t_3) \mid \text{alive at } t_2\} \times \\ &\quad P\{\text{survive } (t_1, t_2) \mid \text{alive at } t_1\} \times \\ &\quad P\{\text{survive } (t_0, t_1) \mid \text{alive at } t_0\} \end{aligned}$$

Likelihood contribution from one individual is a **product** of terms.

Each term refers to one empirical rate (d, y)
with $y = t_{i+1} - t_i$ (mostly $d = 0$).

t_i is a **covariate**

Likelihood for rates (likelihood)

24 / 332

Likelihood for an empirical rate

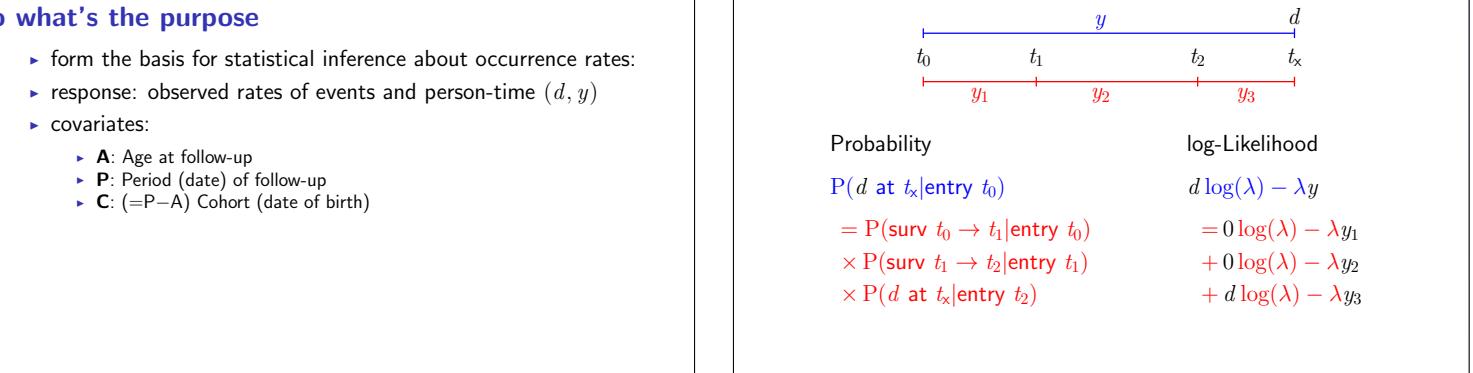

- Likelihood depends on **data** and the **model**
- Model: the rate (λ) is constant in the interval.
- The interval should be sufficiently small for this assumption to be reasonable.

$$\begin{aligned} L(\lambda|y, d) &= P\{\text{survive } y\} \times P\{\text{event}\}^d \\ &= e^{-\lambda y} \times (\lambda dt)^d \\ &= \lambda^d e^{-\lambda y} \end{aligned}$$

$$\ell(\lambda|y, d) = d \log(\lambda) - \lambda y$$

Likelihood for rates (likelihood)

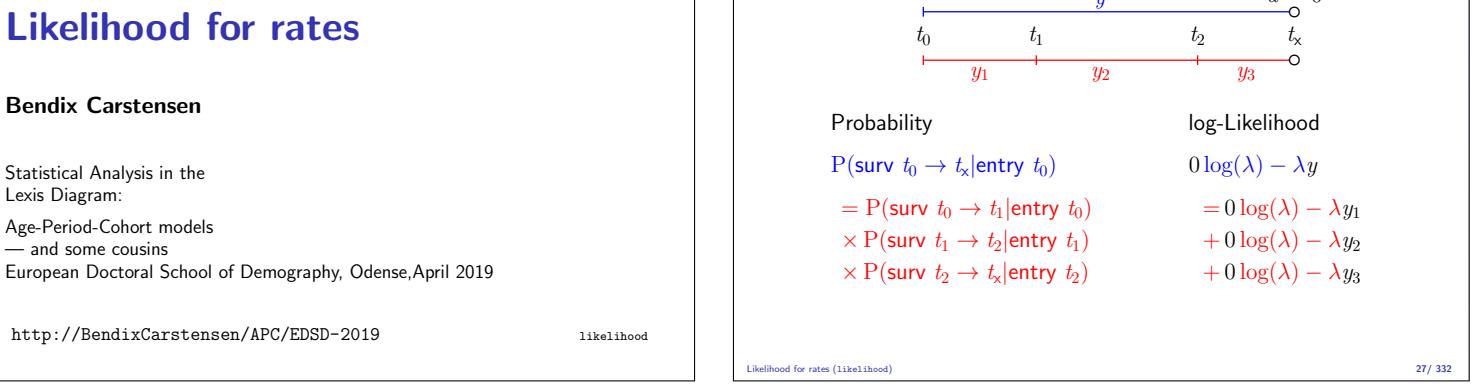

25 / 332

Rates and Survival (surv-rate)

Likelihood for rates (likelihood)

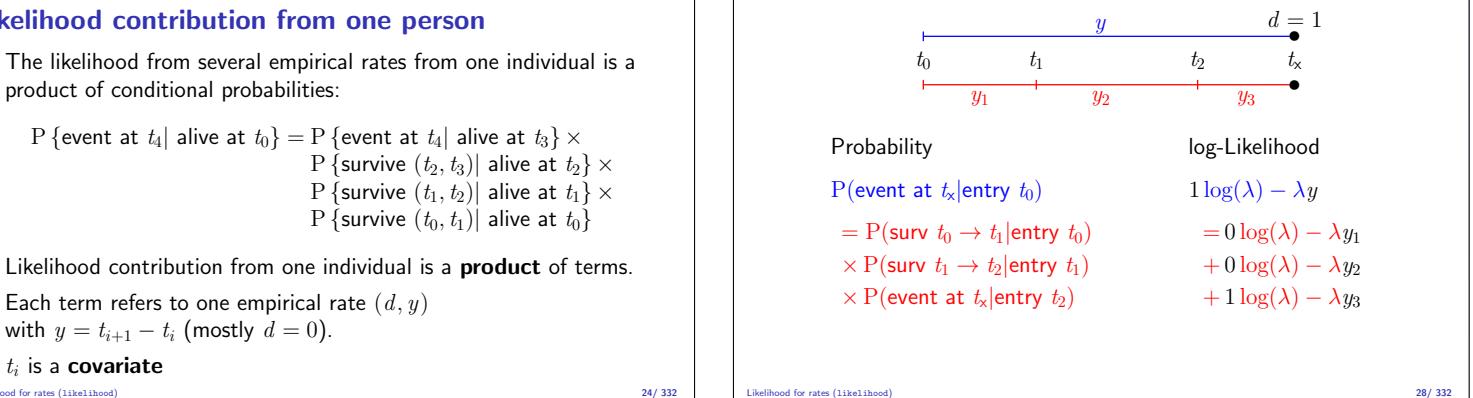

26 / 332

Rates and Survival (surv-rate)

Likelihood for rates (likelihood)

27 / 332

Likelihood for rates (likelihood)

Likelihood for rates (likelihood)

28 / 332

Aim of dividing time into bands:

- Compute rates in different bands of:

- age
- calendar time
- disease duration
- ...

- Allow rates to vary along the timescale:

$$\begin{aligned} 0 \log(\lambda_1) - \lambda_1 y_1 \\ + 0 \log(\lambda_2) - \lambda_2 y_2 \\ + d \log(\lambda_3) - \lambda_3 y_3 \end{aligned} \rightarrow \begin{aligned} 0 \log(\lambda_1) - \lambda_1 y_1 \\ + 0 \log(\lambda_2) - \lambda_2 y_2 \\ + d \log(\lambda_3) - \lambda_3 y_3 \end{aligned}$$

Likelihood for rates (likelihood)

Likelihood for rates (likelihood)

29 / 332

Log-likelihood from more persons

- One person p , different times t : $\sum_t (d_{pt} \log(\lambda_t) - \lambda_t y_{pt})$
- More persons: $\sum_p \sum_t (d_{pt} \log(\lambda_t) - \lambda_t y_{pt})$
- Collect terms with identical values of λ_t :

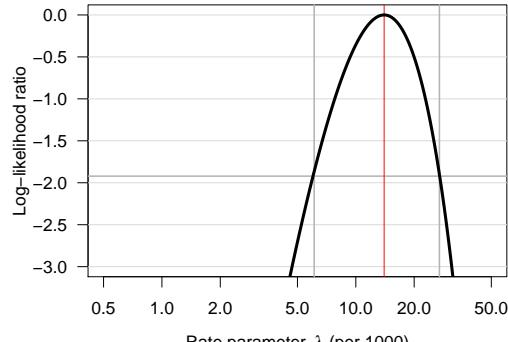

$$\begin{aligned}\sum_t \sum_p (d_{pt} \log(\lambda_t) - \lambda_t y_{pt}) &= \sum_t \left((\sum_p d_{pt}) \log(\lambda_t) - \lambda_t \sum_p y_{pt} \right) \\ &= \sum_t (D_t \log(\lambda_t) - \lambda_t Y_t)\end{aligned}$$

- All events in interval t ("at" time t), D_t
- All exposure time in interval t ("at" time t), Y_t

Likelihood for rates (likelihood)

30 / 332

Log-likelihood ratio

36 / 332

Likelihood example

- Assuming the rate (intensity) is constant, λ ,
- the probability of observing 7 deaths in the course of 500 person-years:

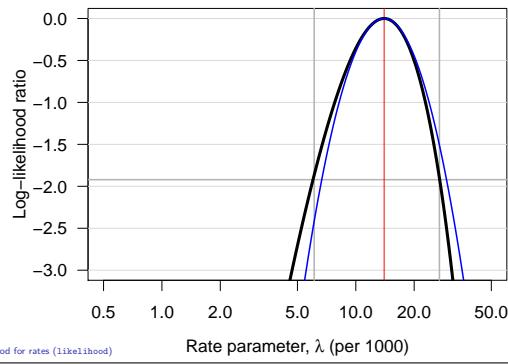

$$\begin{aligned}P\{D = 7, Y = 500 | \lambda\} &= \lambda^D e^{\lambda Y} \times K \\ &= \lambda^7 e^{\lambda 500} \times K \\ &= L(\lambda | \text{data})\end{aligned}$$

- Best guess of λ is where this function is as large as possible.
- Confidence interval is where it is not too far from the maximum

Likelihood for rates (likelihood)

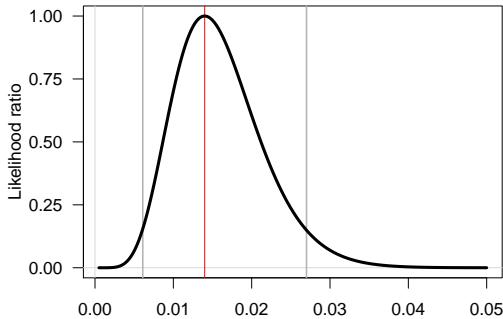

31 / 332

Log-likelihood ratio

37 / 332

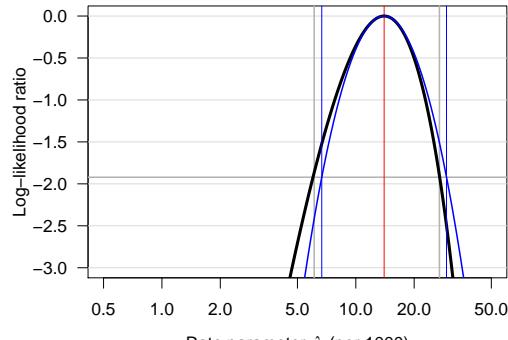

Likelihood-ratio function

Likelihood for rates (likelihood)

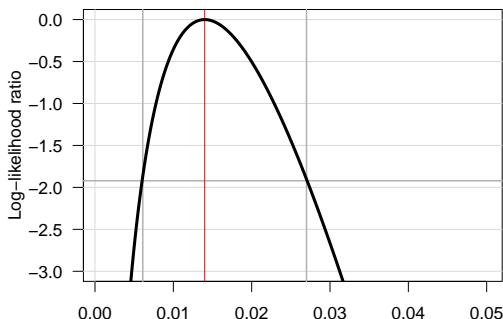

33 / 332

Log-likelihood ratio

38 / 332

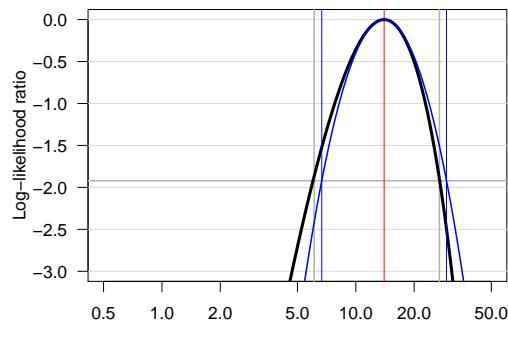

Log-likelihood ratio

Likelihood for rates (likelihood)

34 / 332

Log-likelihood ratio

39 / 332

Poisson likelihood

Log-likelihood from **follow-up** of **one individual**, p , in interval t :

$$\ell_{\text{FU}}(\lambda|d, y) = d_{pt} \log(\lambda(t)) - \lambda(t)y_{pt}, \quad t = 1, \dots, t_p$$

Log-likelihood from a **Poisson observation** d_{pt} with mean

$$\mu = \lambda(t)y_{pt}$$

$$\begin{aligned}\ell_{\text{Poisson}}(\lambda|d) &= d_{pt} \log(\lambda(t)y_{pt}) - \lambda(t)y_{pt} \\ &= \ell_{\text{FU}}(\lambda|d, y) + d_{pt} \log(y_{pt})\end{aligned}$$

Extra term does not depend on the rate parameter λ .

Likelihood for rates (likelihood)

40 / 332

The log-likelihood is maximal for:

$$\frac{d\ell(\lambda)}{d\lambda} = \frac{D}{\lambda} - Y = 0 \Leftrightarrow \hat{\lambda} = \frac{D}{Y}$$

Information about the rate itself, λ :

$$\ell(\lambda|D, Y) = D \log(\lambda) - \lambda Y \quad \ell'_{\lambda} = \frac{D}{\lambda} - Y \quad \ell''_{\lambda} = -\frac{D}{\lambda^2}$$

so $I(\hat{\lambda}) = D/\hat{\lambda}^2 = Y^2/D$, hence $\text{var}(\hat{\lambda}) = D/Y^2$

Standard error of a rate: \sqrt{D}/Y .

Likelihood for rates (likelihood)

44 / 332

Poisson likelihood

Log-likelihood contribution from **one individual**, p , say, is:

$$\ell_{\text{FU}}(\lambda|d, y) = \sum_t (d_{pt} \log(\lambda(t)) - \lambda(t)y_{pt})$$

- ▶ The terms in the sum are **not** independent,
- ▶ but the log-likelihood is a **sum** of Poisson-like terms,
- ▶ the **same** as a likelihood for **independent** Poisson variates, d_{pt}
- ▶ with mean $\mu = \lambda_t y_{pt} \Leftrightarrow \log \mu = \log(\lambda_t) + \log(y_{pt})$
- ⇒ Analyze rates λ based on empirical rates (d, y) as a Poisson model for independent variates where:
 - ▶ d_{pt} is the response variable.
 - ▶ $\log(y_{pt})$ is the offset variable.

Likelihood for rates (likelihood)

41 / 332

Confidence interval for a rate

A 95% confidence interval for the log of a rate is:

$$\hat{\lambda} \pm 1.96/\sqrt{D} = \log(\lambda) \pm 1.96/\sqrt{D}$$

Take the exponential to get the confidence interval for the rate:

$$\lambda \stackrel{x}{\div} \underbrace{\exp(1.96/\sqrt{D})}_{\text{error factor, erf}}$$

Alternatively do the c.i. directly on the rate scale:

$$\lambda \pm 1.96\sqrt{D}/Y$$

Likelihood for rates (likelihood)

45 / 332

Likelihood for follow-up of many subjects

Adding empirical rates over the follow-up of persons:

$$D = \sum d \quad Y = \sum y \quad \Rightarrow \quad D \log(\lambda) - \lambda Y$$

- ▶ Persons are assumed independent
- ▶ Contribution from the same person are **conditionally** independent, hence give separate contributions to the log-likelihood.
- ▶ Follow-up **model** and Poisson **model** are different
- ▶ ... but the **likelihoods** are the same.

Likelihood for rates (likelihood)

42 / 332

Exercise

Suppose we have 17 deaths during 843.6 years of follow-up.

Calculate the mortality rate with a 95% c.i.

Likelihood for rates (likelihood)

46 / 332

The log-likelihood is maximal for:

$$\frac{d\ell(\lambda)}{d\lambda} = \frac{D}{\lambda} - Y = 0 \Leftrightarrow \hat{\lambda} = \frac{D}{Y}$$

Information about the log-rate $\theta = \log(\lambda)$:

$$\ell(\theta|D, Y) = D\theta - e^{\theta}Y, \quad \ell'_{\theta} = D - e^{\theta}Y, \quad \ell''_{\theta} = -e^{\theta}Y$$

so $I(\hat{\theta}) = e^{\hat{\theta}}Y = \hat{\lambda}Y = D$, hence $\text{var}(\hat{\theta}) = 1/D$

Standard error of log-rate: $1/\sqrt{D}$.

Note that this only depends on the no. events, **not** on the follow-up time.

Likelihood for rates (likelihood)

43 / 332

Rates with glm

```
> library(Epi)
> D <- 17
> Y <- 843.6/1000
> round( ci.exp( glm( D ~ 1, offset=log(Y), family=poisson ) ), 2 )
   exp(Est.) 2.5% 97.5%
   (Intercept) 20.15 12.53 32.42
> round( ci.exp( glm( D/Y ~ 1, weight=Y, family=poisson ) ), 2 )
   exp(Est.) 2.5% 97.5%
   (Intercept) 20.15 12.53 32.42
> round( ci.exp( glm( D/Y ~ 1, weight= + Exp=FALSE ), 2 ) )
   Estimate 2.5% 97.5%
   (Intercept) 20.15 10.57 29.73
```

Likelihood for rates (likelihood)

48 / 332

Ratio of two rates

If we have observations two rates λ_1 and λ_0 , based on (D_1, Y_1) and (D_0, Y_0) the variance of the log of the ratio of the rates, $\log(RR)$, is:

$$\begin{aligned}\text{var}(\log(RR)) &= \text{var}(\log(\lambda_1/\lambda_0)) \\ &= \text{var}(\log(\lambda_1)) + \text{var}(\log(\lambda_0)) \\ &= 1/D_1 + 1/D_0\end{aligned}$$

As before, a 95% c.i. for the RR is then:

$$\text{RR} \times \exp \left(1.96 \sqrt{\frac{1}{D_1} + \frac{1}{D_0}} \right)$$

error factor

Likelihood for rates (likelihood)

49 / 332

Exercise

Suppose we in group 0 have 17 deaths during 843.6 years of follow-up in one group, and in group 1 have 28 deaths during 632.3 years.

Calculate the rate-ratio between group 1 and 0 with a 95% c.i.

Likelihood for rates (likelihood)

50 / 332

Rate-ratio with glm

```
> library(Epi)
> D <- c(17,28)
> Y <- c(843.6,632.3)/1000
> F <- factor(0:1)
> round( ci.exp( glm( D ~ F,      offset=log(Y), family=poisson ) ), 2 )
      exp(Est.) 2.5% 97.5%
(Intercept) 20.15 12.53 32.42
F1          2.20  1.20  4.01

> round( ci.exp( glm( D ~ F - 1, offset=log(Y), family=poisson ) ), 2 )
      exp(Est.) 2.5% 97.5%
F0          20.15 12.53 32.42
F1          44.28 30.58 64.14
```

Likelihood for rates (likelihood)

52 / 332

Rate-ratio and -difference with glm

```
> round( ci.exp( glm( D/Y ~ F      , weight=Y, family=poisson ) ), 2 )
      exp(Est.) 2.5% 97.5%
(Intercept) 20.15 12.53 32.42
F1          2.20  1.20  4.01

> round( ci.exp( glm( D/Y ~ F      , weight=Y, family=poisson(link="identity")),
+                  Exp=FALSE), 2 )
      Estimate 2.5% 97.5%
(Intercept) 20.15 10.57 29.73
F1          24.13  5.14 43.13

> round( ci.exp( glm( D/Y ~ F - 1, weight=Y, family=poisson(link="identity")),
+                  Exp=FALSE), 2 )
      Estimate 2.5% 97.5%

Lifetables

Bendix Carstensen

Statistical Analysis in the Lexis Diagram:

Age-Period-Cohort models
— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

lifetable

The life table method

The simplest analysis is by the "life-table method":

interval <i>i</i>	alive <i>n_i</i>	dead <i>d_i</i>	cens. <i>l_i</i>		
					<i>p_i</i>
1	77	5	2	5/(77 - 2/2)	= 0.066
2	70	7	4	7/(70 - 4/2)	= 0.103
3	59	8	1	8/(59 - 1/2)	= 0.137

$$\begin{aligned}p_i &= P\{\text{death in interval } i\} = 1 - d_i/(n_i - l_i/2) \\ S(t) &= (1 - p_1) \times \cdots \times (1 - p_t)\end{aligned}$$

Lifetables (lifetable)

54 / 332

The life table method

The life-table method computes survival probabilities for each time interval, in demography normally one year.

The rate is the number of deaths d_i divided by the risk time $(n_i - d_i/2 - l_i/2) \times \ell_i$:

$$\lambda_i = \frac{d_i}{(n_i - d_i/2 - l_i/2) \times \ell_i}$$

and hence the death probability:

$$p_i = 1 - \exp - \lambda_i \ell_i = 1 - \exp \left(- \frac{d_i}{(n_i - d_i/2 - l_i/2)} \right)$$

The modified life-table estimator.

Lifetables (lifetable)

Lifetables (lifetable)

57 / 332

Observations for the lifetable

Lifetables (lifetable)

Life table is based on person-years and deaths accumulated in a short period.

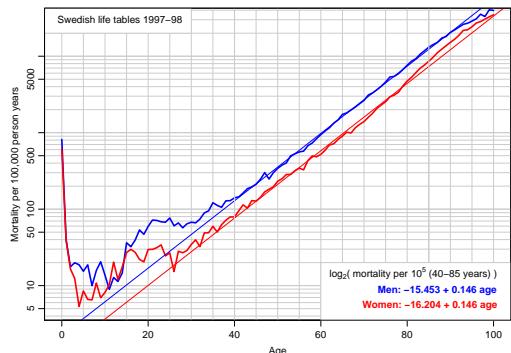

Age-specific rates — cross-sectional!

Survival function:

$$S(t) = e^{-\int_0^t \lambda(a) da} = e^{-\sum_0^t \lambda(a)}$$

— assumes stability of rates to be interpretable for actual persons.

61 / 332

Lifetables (lifetable)

58 / 332

Life table approach

The observation of interest is **not** the survival time of the individual.

It is the **population** experience:

D: Deaths (events).

Y: Person-years (risk time).

The classical lifetable analysis compiles these for prespecified intervals of age, and computes age-specific mortality **rates**.

Data are collected cross-sectionally, but interpreted longitudinally.

Lifetables (lifetable)

62 / 332

Practical

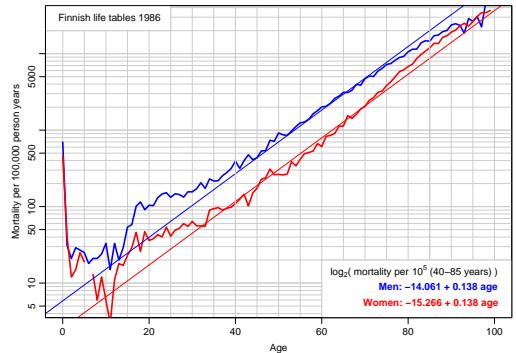

Based on the previous slides answer the following for both Danish and Swedish life tables:

- ▶ What is the doubling time for mortality?
- ▶ What is the rate-ratio between males and females?
- ▶ How much older should a woman be in order to have the same mortality as a man?

Lifetables (lifetable)

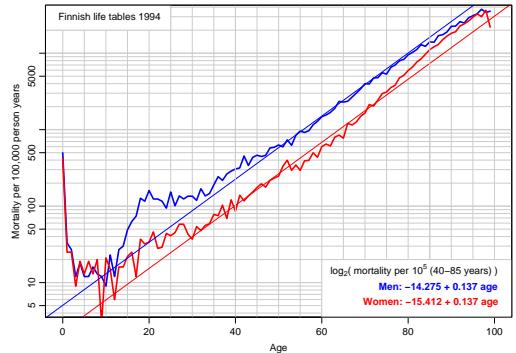

59 / 332

Rates vary over time:

63 / 332

Rates vary over time:

63 / 332

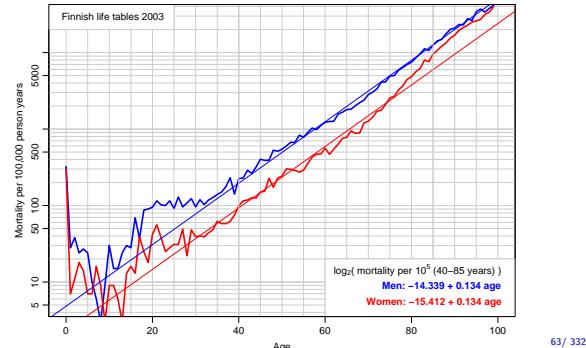

Denmark	Males	Females
$\log_2(\lambda(a))$	$-14.244 + 0.135 \text{ age}$	$-14.877 + 0.135 \text{ age}$
Doubling time	$1/0.135 = 7.41 \text{ years}$	
M/F rate-ratio	$2^{-14.244+14.877} = 2^{0.633} = 1.55$	
Age-difference	$(-14.244 + 14.877)/0.135 = 4.69 \text{ years}$	

Sweden:	Males	Females
$\log_2(\lambda(a))$	$-15.453 + 0.146 \text{ age}$	$-16.204 + 0.146 \text{ age}$
Doubling time	$1/0.146 = 6.85 \text{ years}$	
M/F rate-ratio	$2^{-15.453+16.204} = 2^{0.751} = 1.68$	
Age-difference	$(-15.453 + 16.204)/0.146 = 5.14 \text{ years}$	

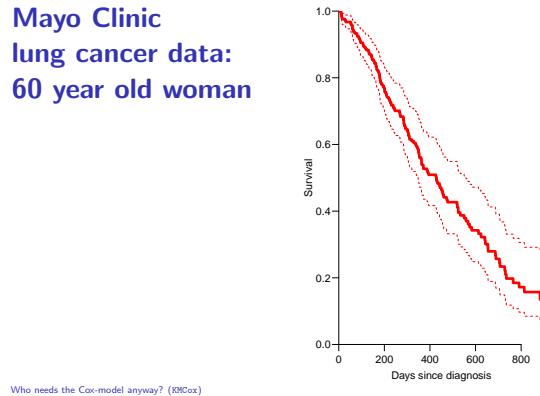

Lifetables (lifetable)

KMCox

A look at the Cox model

$$\lambda(t, x) = \lambda_0(t) \times \exp(x' \beta)$$

A model for the rate as a function of t and x .

Covariates:

- ▶ x
- ▶ t
- ▶ ... often the effect of t is ignored (forgotten?)
- ▶ i.e. left unreported

Who needs the Cox-model anyway? (KMCox)

64 / 332

Splitting the dataset a priori

- ▶ The Poisson approach needs a dataset of empirical rates (d, y) with suitably small values of y .
- ▶ — each individual contributes many empirical rates
- ▶ (one per risk-set contribution in Cox-modeling)
- ▶ From each empirical rate we get:
 - ▶ Poisson-response d
 - ▶ Risk time $y \rightarrow \log(y)$ as offset
 - ▶ time scale covariates: current age, current date, ...
 - ▶ other covariates
- ▶ Contributions not independent, but likelihood is a product
- ▶ Same likelihood as for independent Poisson variates
- ▶ Poisson glm with spline/factor effect of time

Who needs the Cox-model anyway? (KMCox)

67 / 332

Example: Mayo Clinic lung cancer

- ▶ Survival after lung cancer
- ▶ Covariates:
 - ▶ Age at diagnosis
 - ▶ Sex
 - ▶ Time since diagnosis
- ▶ Cox model
- ▶ Split data:
 - ▶ Poisson model, time as factor
 - ▶ Poisson model, time as spline

Who needs the Cox-model anyway? (KMCox)

68 / 332

The Cox-likelihood as profile likelihood

- ▶ One parameter per death time to describe the effect of time (i.e. the chosen timescale).

$$\log(\lambda(t, x_i)) = \log(\lambda_0(t)) + \underbrace{\beta_1 x_{1i} + \cdots + \beta_p x_{pi}}_{\eta_i} = \alpha_t + \eta_i$$

- ▶ Profile likelihood:

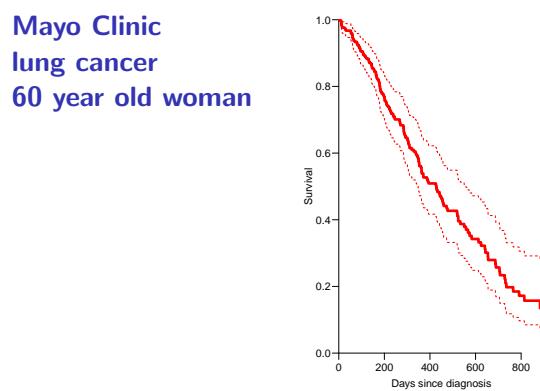

- ▶ Derive estimates of α_t as function of data and β s
— assuming constant rate between death/censoring times
- ▶ Insert in likelihood, now only a function of data and β s
- ▶ This turns out to be Cox's partial likelihood

- ▶ Cumulative intensity ($\Lambda_0(t)$) obtained via the Breslow-estimator

Who needs the Cox-model anyway? (KMCox)

65 / 332

Mayo Clinic lung cancer 60 year old woman

Example: Mayo Clinic lung cancer I

```
> library(survival)
> library(Epi)
> Lung <- Lexis( exit = list( tfe=time ),
+                 exit.status = factor(status,labels=c("Alive","Dead")),
+                 data = lung )
NOTE: entry.status has been set to "Alive" for all.
NOTE: entry is assumed to be 0 on the tfe timescale.
> summary(Lung)

Who needs the Cox-model anyway? (90Cox)

77 / 332

Follow-up data (time-split)

What the Cox-model really is

Taking the life-table approach *ad absurdum* by:

- ▶ dividing time very finely and
- ▶ modeling one covariate, the time-scale, with one parameter per distinct value.
- ▶ the **model** for the time scale is really with exchangeable time-intervals.
- ⇒ difficult to access the baseline hazard (which looks terrible)
- ⇒ uninitiated tempted to show survival curves where irrelevant

Code and output for the entire example available in
<http://bendixcarstensen.com/AdvCoh/WNtCMa/>

Who needs the Cox-model anyway? (90Cox)

78 / 332

Follow-up data (time-split)

81 / 332

Models of this world

- ▶ Replace the α_i s by a parametric function $f(t)$ with a limited number of parameters, for example:
 - ▶ Piecewise constant
 - ▶ Splines (linear, quadratic or cubic)
 - ▶ Fractional polynomials
- ▶ the two latter brings model into "this world":
 - ▶ smoothly varying rates
 - ▶ parametric closed form representation of baseline hazard
 - ▶ finite no. of parameters
- ▶ Makes it really easy to use rates directly in calculations of
 - ▶ expected residual life time
 - ▶ state occupancy probabilities in multistate models
 - ▶ ...

Who needs the Cox-model anyway? (90Cox)

Statistical Analysis in the Lexis Diagram:

Age-Period-Cohort models

— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

Who needs the Cox-model anyway? (90Cox)

76 / 332

Follow-up and rates

- ▶ In follow-up studies we estimate rates from:
 - ▶ D — events, deaths
 - ▶ Y — person-years
 - ▶ $\hat{\lambda} = D/Y$ rates
 - ▶ ... empirical counterpart of intensity — **estimate**
- ▶ Rates differ between persons.
- ▶ Rates differ **within** persons:
 - ▶ By age
 - ▶ By calendar time
 - ▶ By disease duration
 - ▶ ...
- ▶ Multiple timescales.
- ▶ Multiple states (little boxes — later)

Follow-up data (time-split)

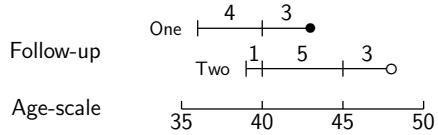

80 / 332

Examples: stratification by age

If follow-up is rather short, age at entry is OK for age-stratification.

If follow-up is long, use stratification by categories of **current age**, both for:

No. of events, D , and Risk time, Y .

— assuming a constant rate λ throughout.

Follow-up data (time-split)

81 / 332

Representation of follow-up data

A cohort or follow-up study records:

Events and **Risk time**.

The outcome is thus **bivariate**: (d, y)

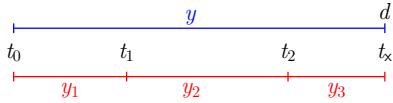

Follow-up **data** for each individual must therefore have (at least) three variables:

Date of entry	entry	date variable
Date of exit	exit	date variable
Status at exit	fail	indicator (0/1)

Specific for each **type** of outcome.

Follow-up data (time-split)

82 / 332

Probability log-Likelihood

$$\begin{aligned} P(d \text{ at } t_x \text{ | entry } t_0) &= d \log(\lambda) - \lambda y \\ &= P(\text{surv } t_0 \rightarrow t_1 \text{ | entry } t_0) = 0 \log(\lambda_1) - \lambda_1 y_1 \\ &\times P(\text{surv } t_1 \rightarrow t_2 \text{ | entry } t_1) + 0 \log(\lambda_2) - \lambda_2 y_2 \\ &\times P(d \text{ at } t_x \text{ | entry } t_2) + d \log(\lambda_3) - \lambda_3 y_3 \end{aligned}$$

— allows different rates (λ_i) in each interval

Follow-up data (time-split)

83 / 332

Age	subj. 1		subj. 2		subj. 3		$\sum Y$	$\sum D$	
	Y	D	Y	D	Y	D			
0–	0.00	0	0.00	0	5.46	0	5.46	0	
10–	6.94	0	1.56	0	1.12	1	8.62	1	
20–	10.00	0	10.00	0	0.00	0	20.00	0	
30–	10.00	0	10.00	0	0.00	0	20.00	0	
40–	4.95	1	1.14	0	0.00	0	6.09	1	
	\sum	31.89	1	22.70	0	6.58	1	60.17	2

Follow-up data (time-split)

87 / 332

Dividing time into bands:

If we want to compute D and Y in intervals on some timescale we must decide on:

Origin: The date where the time scale is 0:

- ▶ Age — 0 at date of birth
- ▶ Disease duration — 0 at date of diagnosis
- ▶ Occupation exposure — 0 at date of hire

Intervals: How should it be subdivided:

- ▶ 1-year classes? 5-year classes?
- ▶ Equal length?

Aim: Separate rate in each interval

Follow-up data (time-split)

84 / 332

Example: cohort with 3 persons:

Id	Bdate	Entry	Exit	St
1	14/07/1952	04/08/1965	27/06/1997	1
2	01/04/1954	08/09/1972	23/05/1995	0
3	10/06/1987	23/12/1991	24/07/1998	1

- ▶ Age bands: 10-years intervals of current age.
- ▶ Split Y for every subject accordingly
- ▶ Treat each segment as a separate unit of observation.
- ▶ Keep track of exit status in each interval.

Follow-up data (time-split)

85 / 332

Timescales

- ▶ A timescale is a variable that varies **deterministically** *within* each person during follow-up:
 - ▶ Age
 - ▶ Calendar time
 - ▶ Time since treatment
 - ▶ Time since relapse
- ▶ All timescales advance at the same pace
(1 year per year ...)
- ▶ Note: Cumulative exposure is **not** a timescale.

Follow-up on several timescales

- ▶ The risk-time is the same on all timescales
- ▶ Only need the entry point on each time scale:
 - ▶ Age at entry.
 - ▶ Date of entry.
 - ▶ Time since treatment at entry.
— if time of treatment is the entry, this is 0 for all.
- ▶ **Response variable** in analysis of rates:
 (d, y) (event, duration)
- ▶ **Covariates** in analysis of rates:
 - ▶ timescales
 - ▶ other (fixed) measurements
- ▶ ... do not confuse **duration** and **timescale** !

Follow-up data (time-split)

89 / 332

Splitting the follow up

	subj. 1	subj. 2	subj. 3
Age at Entry:	13.06	18.44	4.54
Age at eXit:	44.95	41.14	11.12
Status at exit:	Dead	Alive	Dead
	—	—	—
Y	31.89	22.70	6.58
D	1	0	1

Follow-up data (time-split)

86 / 332

Follow-up data in Epi — Lexis objects

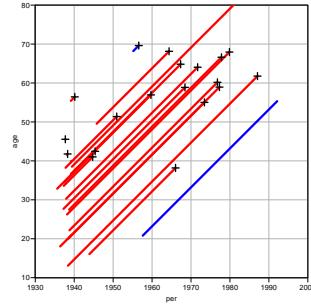

```
> thoro[1:6,1:8]

1  1   2 1916.609      1 1938.791    22 1976.787      1
2  2   2 1927.843      1 1943.906    80 1966.030      1
3  3   1 1902.778      1 1935.629   10 1959.719      1
4  4   1 1918.359      1 1936.396   10 1977.307      1
5  5   1 1902.931      1 1937.387   10 1945.387      1
6  6   2 1903.714      1 1937.316   20 1944.738      1
```

Timescales of interest:

- ▶ Age
- ▶ Calendar time
- ▶ Time since injection

Follow-up data (time-split)

91 / 332

```
> plot( thL, 2:1, lwd=5, col=c("red","blue")[thL$contrast],
+       grid=TRUE, lty.grid=1, col.grid=gray(0.7),
+       xlim=1930+c(0,70), xaxs="i", ylim= 10+c(0,70), yaxs="i", las=1 )
> points( thL, 2:1, pch=c(NA,3)[thL$lex.Xst+1],lwd=3, cex=1.5 )
```

Follow-up data (time-split)

95 / 332

Definition of Lexis object

```
thL <- Lexis( entry = list( age = injecdat-birthdat,
                           per = injecdat,
                           tfi = 0 ),
               exit = list( per = exitdat ),
               exit.status = as.numeric(exitstat==1),
               data = thoro )
```

entry is defined on **three** timescales,
but **exit** is only needed on **one** timescale:

Follow-up time is the same on all timescales:

$$\text{exitdat} - \text{injecdat}$$

One element of entry and exit must have same name (**per**).

Likelihood for a constant rate

- This setup is for a situation where it is assumed that rates are constant in each of the intervals.
- Each observation in the dataset contributes a term to the likelihood.
- Each term looks like a contribution from a Poisson variate (albeit with values only 0 or 1)
- Rates can vary along several timescales simultaneously.
- Models can include fixed covariates, as well as the timescales (the left end-points of the intervals) as **quantitative** variables.
- The latter is where we will need splines.

Follow-up data (time-split)

99 / 332

The Poisson likelihood for split data

- Split records (one per person-interval (p, i)):

$$\sum_{p,i} (d_{pi} \log(\lambda) - \lambda y_{pi}) = D \log(\lambda) - \lambda Y$$

- Assuming that the death indicator ($d_{pi} \in \{0,1\}$) is Poisson, a model with offset $\log(y_{pi})$ will give the same result.
- If we assume that rates are constant we get the simple expression with (D, Y)
- ... but the split data allows models that assume different rates for different (d_{pi}, y_{pi}), so rates can vary **within** a person's follow-up.

Follow-up data (time-split)

100 / 332

Where is (d_{pi}, y_{pi}) in the split data?

```
> spl1 <- splitLexis( thL , breaks=seq(0,100,20) , time.scale="age" )
> spl2 <- splitLexis( spl1 , breaks=c(0,1,5,20,100) , time.scale="tfi" )
> options( digits=5 )
> spl2[1:10,1:11]

— not the printing: it's a `data.table`

Follow-up data (time-split)

102 / 332

Analysis of results

- d_{pi} — events in the variable: `lex.Xst`:
In the model as response: `lex.Xst==1`
- y_{pi} — risk time: `lex.dur` (duration):
In the model as offset $\log(y)$, $\log(\text{lex.dur})$.
- Covariates are:
 - timescales (age, period, time in study)
 - other variables for this person (constant or *assumed* constant in each interval).
- Model rates using the covariates in `glm`:
 - no difference between time-scales and other covariates.

tab-mod

Lexis diagram¹

Disease registers record events.

Official statistics collect population data.

¹ Named after the German statistician and economist William Lexis (1837–1914), who devised this diagram in the book "Einleitung in die Theorie der Bevölkerungsstatistik" (Karl J. Trübner, Strassburg, 1875).

109 / 332

Conceptual set-up

Follow-up of the entire (male) population from 1943–2006 w.r.t. occurrence of testis cancer:

- ▶ Split follow-up time for all about 4 mil. men in 1-year classes by age and calendar time (y).
- ▶ Allocate testis cancer event ($d = 0, 1$) to each.
- ▶ Analyze all 200,000,000 records by a Poisson model.

Models for tabulated data (tab-mod)

106 / 332

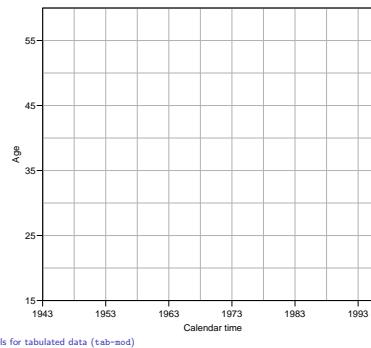

Realistic set-up

- ▶ Tabulate the follow-up time and events by age and period.
- ▶ 100 age-classes.
- ▶ 65 periods (single calendar years).
- ▶ 6500 aggregate records of (D , Y).
- ▶ Analyze by a Poisson model.

Models for tabulated data (tab-mod)

107 / 332

Lexis diagram

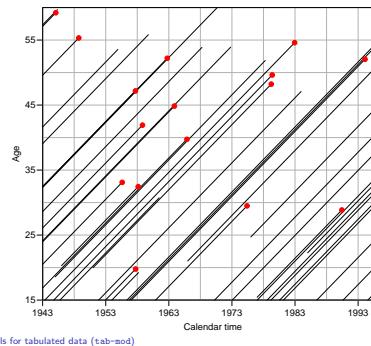

Registration of:
cases (D)

risk time,
person-years (Y)

in subsets of the Lexis diagram.

109 / 332

Lexis diagram

Registration of:
cases (D)
risk time,
person-years (Y)
in subsets of the Lexis diagram.

Rates available in each subset.

111 / 332

Practical set-up

- ▶ Tabulate only events (as obtained from the cancer registry) by age and period.
- ▶ 100 age-classes.
- ▶ 65 periods (single calendar years).
- ▶ 6500 aggregate records of D .
- ▶ Estimate the population follow-up based on census data from Statistics Denmark (Y_{pop}).
... or get it from the human mortality database.
- ▶ If disease is common: tabulate follow-up **after** diagnosis (Y_{dis}), and subtract from population follow-up.
- ▶ Analyze (D , Y) by Poisson model.

Models for tabulated data (tab-mod)

Models for tabulated data (tab-mod)

117 / 332

Tabulated data

Once data are in tabular form, models are restricted:

- Rates must be assumed constant in each cell of the table / subset of the Lexis diagram.
- With large cells (5×5 years) it is customary to put a separate parameter on each cell or on each levels of classifying factors.
- Output from the model will be rates and rate-ratios.
- Since we use multiplicative Poisson, usually the log rates and the log-RR are reported

Models for tabulated data (tab-mod)

114 / 332

Linear combinations of the parameters can be computed using the `ctr.mat` option:

```
> CM <- rbind( '1943 vs. 1953' = c( 0, -1, 0 ),
+               '1948 vs. 1953' = c( 1, -1, 0 ),
+               'Ref. (1953)' = c( 0, 0, 0 ),
+               '1958 vs. 1953' = c( 0, -1, 1 ) )
> round( ci.exp( m0, subset="P", ctr.mat=CM ), 3 )
   exp(Est.) 2.5% 97.5%
1943 vs. 1953    0.682 0.543 0.857
1948 vs. 1953    0.813 0.655 1.010
Ref. (1953)      1.000 1.000 1.000
1958 vs. 1953    1.087 0.887 1.332
```

Models for tabulated data (tab-mod)

118 / 332

Simple age-period model for the testis cancer rates:

```
> m0 <- glm( D ~ factor(A) + factor(P) + offset( log(Y/10^5) ),
+            family=poisson, data=ts )
> summary( m0 )

Call:
glm(formula = D ~ factor(A) + factor(P) + offset(log(Y/10^5)),
      family = poisson, data = ts)

Deviance Residuals:
    Min      1Q  Median      3Q      Max
-1.5991 -0.6974  0.1284  0.6671  1.8904

Coefficients:
             Estimate Std. Error z value Pr(>|z|)
(Intercept) -1.4758    0.3267 -4.517 6.26e-06
factor(A)20  1.4539    0.3545  4.101 4.11e-05

Age-Period and Age-Cohort models (AP-AC)

124 / 332

The classical plots

Given a table of rates classified by age and period, we can do 4 "classical" plots:

- ▶ Rates versus age at diagnosis (period):
 - rates in the same age-class connected.
- ▶ Rates versus age at diagnosis:
 - rates in the same birth-cohort connected.
- ▶ Rates versus date of diagnosis:
 - rates in the same age-class connected.
- ▶ Rates versus date of date of birth:
 - rates in the same age-class connected.

These plots can be produced by the R-function `rateplot`.

Estimates from Age-Cohort model

Age-Period and Age-Cohort models (AP-AC)

144 / 332

Linear effect of period:

$$\log[\lambda(a, p)] = \alpha_a + \beta_p = \alpha_a + \beta(p - p_0)$$

that is, $\beta_p = \beta(p - p_0)$.

Linear effect of cohort:

$$\log[\lambda(a, p)] = \tilde{\alpha}_a + \gamma_c = \tilde{\alpha}_a + \gamma(c - c_0)$$

that is, $\gamma_c = \gamma(c - c_0)$

Age-drift model (Ad)

147 / 332

Recap of Monday — rates

- Rate, intensity: $\lambda(t) = P\{ \text{event in } (t, t+h) | \text{alive at } t \} / h$
- Observe empirical rates (d, y) — possibly many per person.
- $\ell_{FU} = d\log(\lambda) - \lambda y$, obs: (d, y) , rate par: λ
- $\ell_{Poisson} = d\log(\lambda y) - \lambda y$, obs: d , mean par: $\mu = \lambda y$
- $\ell_{Poisson} - \ell_{FU} = d\log(y)$ does not involve λ
— use either to find m.l.e. of λ
- Poisson model is for $\log(\mu) = \log(\lambda y) = \log(\lambda) + \log(y)$
hence offset= $\log(Y)$
- Once rates are known, we can construct survival curves and derivatives of that.

Age-Period and Age-Cohort models (AP-AC)

145 / 332

Recap Monday — models

- Empirical rate (d_t, y_t) relates to a **time** t
- Many for the same person — different times
- Not independent, but likelihood is a product
- One parameter per interval \Rightarrow exchangeable times
- Use the quantitative nature of t : \Rightarrow smooth continuous effects of time
- Predicted rates: `ci.pred(model, newdata=nd)`
- RR is the difference between two predictions:
- RR by period:
- `ndx<-data.frame(P=1947:1980, A=47)`
- `ndr<-data.frame(P=1870, A=47)`
- `ci.exp(model, ctr.mat=list(ndx-ndr))`

Age-drift model

Bendix Carstensen

Statistical Analysis in the

Lexis Diagram:

Age-Period-Cohort models

— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

Ad

What goes on?

$$p = a + c \quad p_0 = a_0 + c_0$$

$$\begin{aligned} \alpha_a + \beta(p - p_0) &= \alpha_a + \beta(a + c - (a_0 + c_0)) \\ &= \underbrace{\alpha_a + \beta(a - a_0)}_{\text{cohort age-effect}} + \beta(c - c_0) \end{aligned}$$

The two **models** are the same.

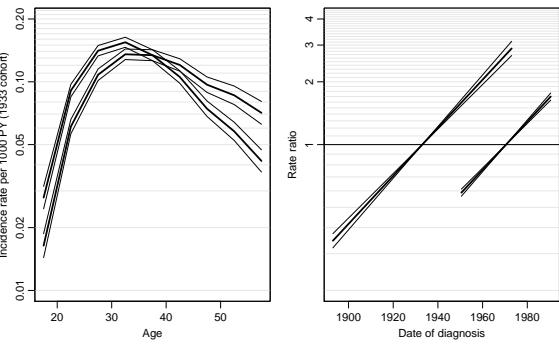

The **parametrization** is different.

The age-curve refers either

- to a period (cross-sectional rates) or
- to a cohort (longitudinal rates).

Age-drift model (Ad)

150 / 332

Which age-curve is period and which is cohort?

APC-cat

The age-period-cohort model

$$\log[\lambda(a, p)] = \alpha_a + \beta_p + \gamma_c$$

- ▶ Three effects:
 - ▶ a — Age (at diagnosis)
 - ▶ p — Period (of diagnosis)
 - ▶ c — Cohort (of birth)
- ▶ No assumptions about the **shape** of effects.
- ▶ Levels of A, P and C are assumed **exchangeable**
- ▶ i.e. no assumptions about the relationship between parameter estimates and the **scaled values** of A, P and C

Age-Period-Cohort model (APC-cat)

156 / 332

Fitting the model in R V

Age-Period-Cohort model (APC-cat)

157 / 332

No. of parameters

A has $9(A)$ levels

P has $10(P)$ levels

C=P-A has $18(C = A + P - 1)$ levels

Age-drift model has $A + 1 = 10$ parameters

Age-period model has $A + P - 1 = 18$ parameters

Age-cohort model has $A + C - 1 = 26$ parameters

Age-period-cohort model has $A + P + C - 3 = 34$ parameters:

```
> length( coef(m.apc) ) ; sum( !is.na(coef(m.apc)) )
[1] 35
[1] 34
```

The missing parameter is because of the **identifiability problem**.

Age-Period-Cohort model (APC-cat)

158 / 332

Test for effects

```
> tc.apc <- apc.fit( tc, model="factor", ref.c=1943, scale=10^5 )
```

Age-Period-Cohort model (APC-cat)

159 / 332

How to choose a parametrization

- Standard approach: Put extremes of periods or cohorts to 0, and choose a reference for the other.
- Clayton & Schiffers: only 2nd order differences are invariants:

$$\alpha_{i-1} - 2\alpha_i + \alpha_{i+1}$$

Implemented in Epi via the contrast type contr.2nd (later).

- Holford: Extract linear effects by regression:

$$\lambda(a, p) = \hat{\alpha}_a + \hat{\beta}_p + \hat{\gamma}_c = \tilde{\alpha}_a + \hat{\mu}_a + \hat{\delta}_a a + \tilde{\beta}_p + \hat{\beta}_p + \hat{\mu}_p + \hat{\delta}_p p + \tilde{\gamma}_c + \hat{\gamma}_c + \hat{\mu}_c + \hat{\delta}_c c$$

Age-Period-Cohort model (APC-cat)

160 / 332

Assumptions

Assumptions are needed to do this, e.g.:

- Age is the major time scale
- Cohort is the secondary time scale (the major secular trend)
- c_0 is the reference cohort
- Period is the residual time scale: 0 on average, 0 slope
- ... constraining first and last period parameter to 0 is a crude way of obtaining this.

Age-Period-Cohort model (APC-cat)

161 / 332

Relocating effects between A, P and C

Period effect, 0 on average, slope is 0: a regression of β_p on p :

$$g(p) = \tilde{\beta}_p = \beta_p - \hat{\mu}_p - \hat{\delta}_p p$$

Cohort effect, absorbing all time-trend ($\delta_p p = \delta_p(a + c)$) and risk relative to c_0 :

$$h(c) = \gamma_c - \gamma_{c_0} + \hat{\delta}_p(c - c_0)$$

The rest is the age-effect:

$$f(a) = \alpha_a + \hat{\mu}_a + \hat{\delta}_p a + \hat{\delta}_p c_0 + \gamma_{c_0}$$

Age-Period-Cohort model (APC-cat)

162 / 332

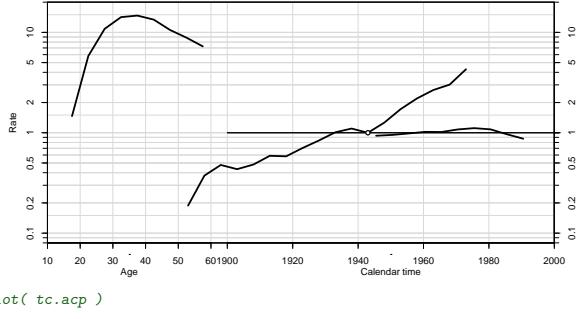

How it all adds up:

$$\begin{aligned} \lambda(a, p) &= \hat{\alpha}_a + \hat{\beta}_p + \hat{\gamma}_c \\ &= \hat{\alpha}_a + \gamma_{c_0} + \hat{\mu}_p + \hat{\delta}_p(a + c_0) + \\ &\quad \hat{\beta}_p - \hat{\mu}_p - \hat{\delta}_p(a + c) + \\ &\quad \hat{\gamma}_c - \gamma_{c_0} + \hat{\delta}_p(c - c_0) \end{aligned}$$

Only the regression on period is needed! (For this model...)

Age-Period-Cohort model (APC-cat)

170 / 332

A simple practical approach

- First fit the age-cohort model, with cohort c_0 as reference and get estimates $\hat{\alpha}_a$ and $\hat{\gamma}_c$:

$$\log[\lambda(a, p)] = \hat{\alpha}_a + \hat{\gamma}_c$$

- Then consider the full APC-model with age and cohort effects constrained to be as estimated from the AC-model:

$$\log[\lambda(a, p)] = \hat{\alpha}_a + \hat{\gamma}_c + \beta_p$$

Age-Period-Cohort model (APC-cat)

167 / 332

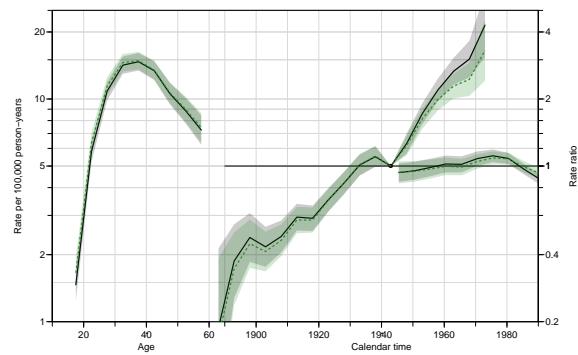

- The residual period effect can be estimated if we note that for the number of cases we have:

$$\log(\text{expected cases}) = \log[\hat{\lambda}(a, p) Y] = \underbrace{\hat{\alpha}_a + \hat{\gamma}_c + \log(Y)}_{\text{"known"}} + \beta_p$$

- This is analogous to the expression for a Poisson model in general,
- ... but now is the offset not just $\log(Y)$ but $\hat{\alpha}_a + \hat{\gamma}_c + \log(Y)$, the log of the fitted values from the age-cohort model.
- β_p s are estimated in a Poisson model with this as offset.
- Advantage: We get the standard errors for free.

```

Age-Period-Cohort model (APC-cat)

169 / 332

Age at entry (diagnosis) as covariate

t : time since entry (duration)

e : age at entry

$a = e + t$: current age (age at follow-up)

Duration as basic time-scale; linear effect of age at entry:

$$\log(\lambda(a, t)) = f(t) + \beta e = (f(t) - \beta t) + \beta a$$

Immaterial whether a or e is used as (log)-linear covariate as long as t is in the model.

Age at entry
Age-Duration-Diagnosis (Age-at-entry)

172 / 332

Non-linear effects of time-scales

Arbitrary effects of the three variables t , a and e :
 ⇒ genuine extension of the model.

$$\log(\lambda(a, t)) = f(t) + g(a) + h(e)$$

Three quantities can be arbitrarily moved between the three functions:

$$\tilde{f}(t) = f(a) - \mu_a - \mu_e + \gamma t$$

$$\tilde{g}(a) = g(p) + \mu_a - \gamma a$$

$$\tilde{h}(e) = h(c) + \mu_a + \gamma e$$

because $t - a + e = 0$.

This is the age-period-cohort modeling problem again.

Age at entry

Tabulation in the Lexis diagram (Lexis-tab)

176 / 332

Controlling for age

— is not a well defined statement:

- ▶ Mostly it means that age **at entry** is included in the model.
- ▶ But ideally one would check whether there were non-linear effects of age at entry and current age.
- ▶ This would require modeling of multiple timescales.
- ▶ Which is best accomplished by splitting follow up and using Poisson models, with time scales as covariates.

Tabulation in the Lexis diagram (Lexis-tab)

179 / 332

Major sets in the Lexis diagram

A-sets: Classification by age and period. (□)

B-sets: Classification by age and cohort. (▽)

C-sets: Classification by cohort and period. (△)

The mean age, period and cohort for these sets is just the mean of the tabulation interval.

The mean of the third variable is found by using $a = p - c$.

Tabulation in the Lexis diagram (Lexis-tab)

180 / 332

Analysis of rates from a complete observation in a Lexis diagram need not be restricted to these classical sets classified by two factors.

We may classify cases and risk time by all three factors

Lexis triangles:

Upper triangles: Classification by age and period, earliest born cohort. (▽)

Lower triangles: Classification by age and period, latest born cohort. (△)

Tabulation in the Lexis diagram (Lexis-tab)

181 / 332

Mean a , p and c during FU in triangles

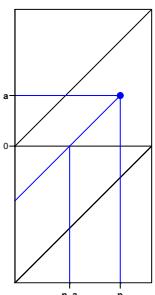

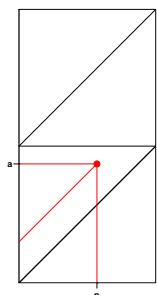

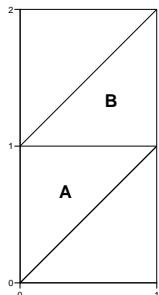

Modeling requires that each set (=observation in the dataset) be assigned a value of age, period and cohort. So for each triangle we need:

- ▶ mean age at risk.
- ▶ mean date at risk.
- ▶ mean cohort at risk.

Tabulation in the Lexis diagram (Lexis-tab)

182 / 332

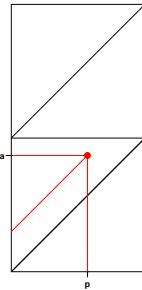

Means in upper (A) and lower (B) triangles:

Tabulation in the Lexis diagram (Lexis-tab)

183 / 332

Upper triangles (▽), A:

$$E_A(a) = \int_{p=0}^{p=1} \int_{a=p}^{a=1} a \times 2 \, da \, dp = \int_{p=0}^{p=1} 1 - p^2 \, dp = \frac{2}{3}$$

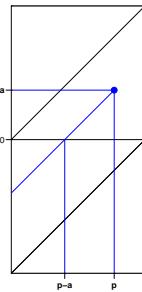

$$E_A(p) = \int_{a=0}^{a=1} \int_{p=0}^{p=a} p \times 2 \, dp \, da = \int_{a=0}^{a=1} a^2 \, da = \frac{1}{3}$$

$$E_A(c) = \frac{1}{3} - \frac{2}{3} = -\frac{1}{3}$$

Tabulation in the Lexis diagram (Lexis-tab)

184 / 332

Lower triangles (△), B:

$$E_B(a) = \int_{p=0}^{p=1} \int_{a=0}^{a=p} a \times 2 \, da \, dp = \int_{p=0}^{p=1} p^2 \, dp = \frac{1}{3}$$

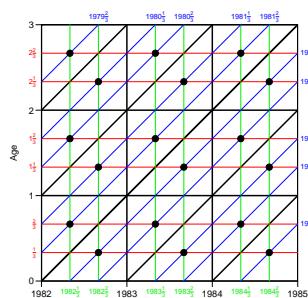

$$E_B(p) = \int_{a=0}^{a=1} \int_{p=a}^{p=1} p \times 2 \, dp \, da = \int_{a=0}^{a=1} 1 - a^2 \, da = \frac{2}{3}$$

$$E_B(c) = \frac{2}{3} - \frac{1}{3} = \frac{1}{3}$$

Tabulation in the Lexis diagram (Lexis-tab)

185 / 332

Tabulation by age, period and cohort

Tabulation in the Lexis diagram (Lexis-tab)

186 / 332

Gives triangular sets with differing mean age, period and cohort:

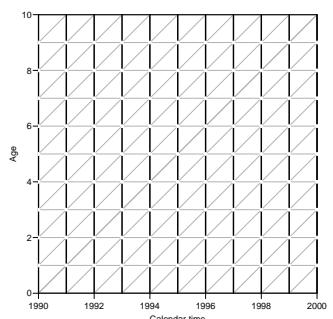

These correct midpoints for age, period and cohort must be used in modeling.

From population figures to risk time

Population figures in the form of size of the population at certain date are available from most statistical bureaus.

This corresponds to population sizes along the vertical lines in the diagram.

We want risk time figures for the population in the squares and triangles in the diagram.

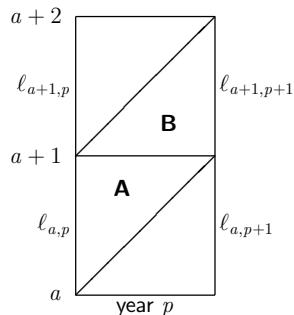

Tabulation in the Lexis diagram (Lexis-tab)

187 / 332

Prevalent population figures

$\ell_{a,p}$ is the number of persons in age class a alive at the beginning of period (=year) p .

The aim is to compute person-years for the triangles **A** and **B**, respectively.

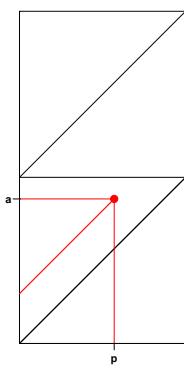

Tabulation in the Lexis diagram (Lexis-tab)

188 / 332

The area of the triangle is $1/2$, so the uniform measure over the triangle has density 2. Therefore a person dying in age a at date p in **A** contributes p risk time in **A**, so the average will be:

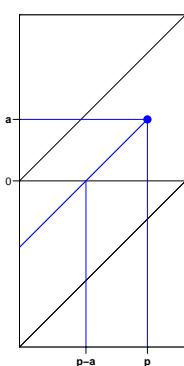

$$\begin{aligned} & \int_{p=0}^{p=1} \int_{a=p}^{a=1} 2p \, da \, dp \\ &= \int_{p=0}^{p=1} 2p - 2p^2 \, dp \\ &= \left[p^2 - \frac{2p^3}{3} \right]_{p=0}^{p=1} = \frac{1}{3} \end{aligned}$$

189 / 332

A person dying in age a at date p in **B** contributes $p - a$ risk time in **A**, so the average will be (again using the density 2 of the uniform measure):

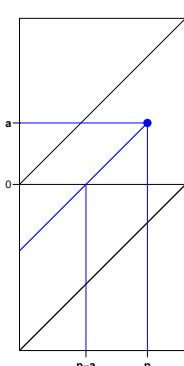

$$\begin{aligned} & \int_{p=0}^{p=1} \int_{a=0}^{a=p} 2(p-a) \, da \, dp \\ &= \int_{p=0}^{p=1} [2pa - a^2]_{a=0}^{a=p} \, dp \\ &= \int_{p=0}^{p=1} p^2 \, dp = \frac{1}{3} \end{aligned}$$

190 / 332

A person dying in age a at date p in **B** contributes a risk time in **B**, so the average will be:

$$\begin{aligned} & \int_{p=0}^{p=1} \int_{a=0}^{a=p} 2a \, da \, dp \\ &= \int_{p=0}^{p=1} p^2 \, dp = \frac{1}{3} \end{aligned}$$

191 / 332

Mean contributions to risk time in **A** and **B**:

A:	B:
Survivors: $\ell_{a+1,p+1} \times \frac{1}{2}y$	$\ell_{a+1,p+1} \times \frac{1}{2}y$
Dead in A : $\frac{1}{2}(\ell_{a,p} - \ell_{a+1,p+1}) \times \frac{1}{3}y$	$\frac{1}{2}(\ell_{a,p} - \ell_{a+1,p+1}) \times \frac{1}{3}y$
Dead in B : $\frac{1}{2}(\ell_{a,p} - \ell_{a+1,p+1}) \times \frac{1}{3}y$	$\frac{1}{2}(\ell_{a,p} - \ell_{a+1,p+1}) \times \frac{1}{3}y$
\sum $(\frac{1}{3}\ell_{a,p} + \frac{1}{6}\ell_{a+1,p+1}) \times 1y$	$(\frac{1}{6}\ell_{a,p} + \frac{1}{3}\ell_{a+1,p+1}) \times 1y$

The number of deaths in **A** and **B** is $\ell_{a,p} - \ell_{a+1,p+1}$, and we assume that half occur in **A** and half in **B**.

Tabulation in the Lexis diagram (Lexis-tab)

192 / 332

Population as of 1. January from Statistics Denmark:

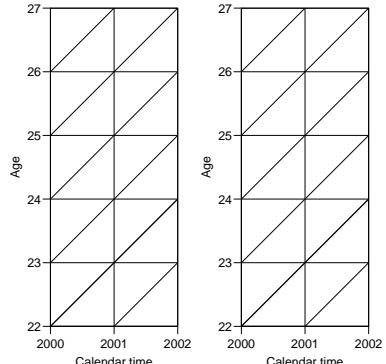

Age	Men			Women		
	2000	2001	2002	2000	2001	2002

26	38194	38048	38341	37292	37371	38119
27	39891	38221	38082	39273	37403	37525

Tabulation in the Lexis diagram (Lexis-tab)

193 / 332

Exercise:

Fill in the risk time figures in as many triangles as possible from the previous table for men and women, respectively.

194 / 332

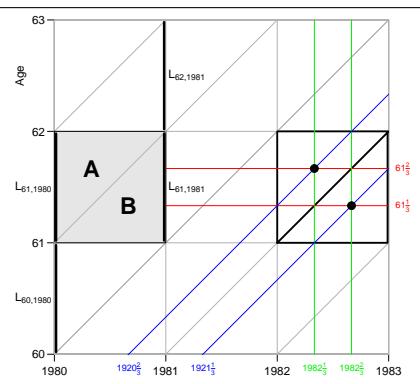

Summary:

Population risk time:

$$\mathbf{A}: (\frac{1}{3}\ell_{a,p} + \frac{1}{6}\ell_{a+1,p+1}) \times 1y$$

$$\mathbf{B}: (\frac{1}{6}\ell_{a-1,p} + \frac{1}{3}\ell_{a,p+1}) \times 1y$$

Mean age, period and cohort:
 $\frac{1}{3}$ into the interval.

195 / 332

APC-model for triangular data

Bendix Carstensen

Statistical Analysis in the Lexis Diagram:
Age-Period-Cohort models
— and some cousins
European Doctoral School of Demography, Odense, April 2019

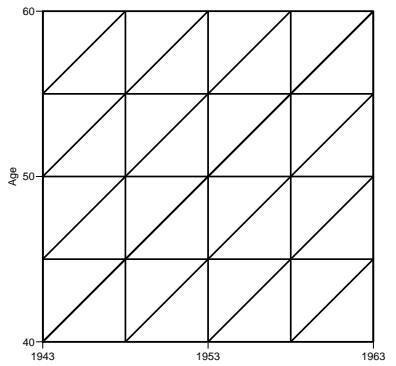

<http://BendixCarstensen/APC/EDSD-2019>

APC-tri

Fill in the number of cases (D) and person-years (Y) from previous slide.

Indicate birth cohorts on the axes for upper and lower triangles.

Mark mean date of birth for these.

APC-model for triangular data (APC-tri)

199 / 332

Model for triangular data

- One parameter per distinct value on each timescale.
- Example: 3 age-classes and 3 periods:

- 6 age parameters
- 6 period parameters
- 10 cohort parameters

- Model:

$$\lambda_{ap} = \alpha_a + \beta_p + \gamma_c$$

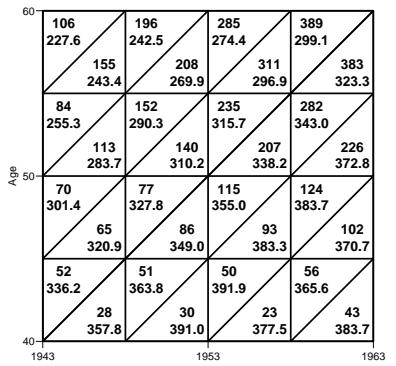

APC-model for triangular data (APC-tri)

196 / 332

Fill in the number of cases (D) and person-years (Y) from previous slide.

Indicate birth cohorts on the axes for upper and lower triangles.

Mark mean date of birth for these.

APC-model for triangular data (APC-tri)

200 / 332

Problem: Disconnected design!

Log-likelihood contribution from one triangle:

$$D_{ap}\log(\lambda_{ap}) - \lambda_{ap} Y_{ap} = D_{ap}\log(\alpha_a + \beta_p + \gamma_c) - (\alpha_a + \beta_p + \gamma_c) Y_{ap}$$

The log-likelihood can be separated:

$$\sum_{a,p \in \nabla} D_{ap}\log(\lambda_{ap}) - \lambda_{ap} Y_{ap} + \sum_{a,p \in \Delta} D_{ap}\log(\lambda_{ap}) - \lambda_{ap} Y_{ap}$$

No common parameters between terms

— we have two separate models:

One for upper triangles, one for lower.

APC-model for triangular data (APC-tri)

197 / 332

APC-model with “synthetic” cohorts

```
> mc <- glm( D ~ factor(A5) - 1 +
+           factor(P5-A5) +
+           factor(P5) + offset( log( Y ) ),
+           family=poisson )
> summary( mc )

...
Null deviance: 1.0037e+08 on 220 degrees of freedom
Residual deviance: 8.8866e+02 on 182 degrees of freedom
```

No. parameters: $220 - 182 = 38$.

$$A = 10, \quad P = 11, \quad C = 20 \quad \Rightarrow \quad A + P + C - 3 = 38$$

APC-model for triangular data (APC-tri)

201 / 332

Illustration by lung cancer data

```
> library( Epi )
> data( lungDK )
> lungDK[1:10,]
   A5  P5  C5 up      Ax      Px      Cx  D    Y

3 40 1948 1903 1 43.33333 1949.667 1906.333 51 363783.7
4 40 1948 1908 0 41.66667 1951.333 1909.667 30 390985.8
5 40 1953 1908 1 43.33333 1954.667 1911.333 50 391925.3
6 40 1953 1913 0 41.66667 1956.333 1914.667 23 377515.3
7 40 1958 1913 1 43.33333 1959.667 1916.333 56 365575.5
8 40 1958 1918 0 41.66667 1961.333 1919.667 43 383689.0
9 40 1963 1918 1 43.33333 1964.667 1921.333 44 385878.5
10 40 1963 1923 0 41.66667 1966.333 1924.667 38 371361.5
```

APC-model for triangular data (APC-tri)

198 / 332

APC-model with “correct” cohorts

```
> mx <- glm( D ~ factor(Ax) - 1 +
+           factor(Cx) +
+           factor(Px) + offset( log( Y ) ),
+           family=poisson )
> summary( mx )

...
Null deviance: 1.0037e+08 on 220 degrees of freedom
Residual deviance: 2.8473e+02 on 144 degrees of freedom
```

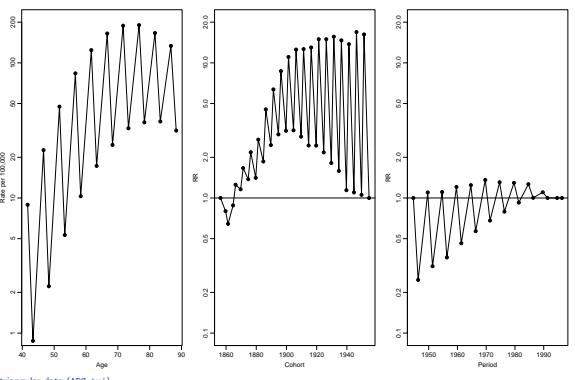

No. parameters: $220 - 144 = 76$ ($= 38 \times 2$).

$$A = 20, \quad P = 22, \quad C = 40 \quad \Rightarrow \quad A + P + C - 3 = 79 \neq 76!$$

We have fitted two age-period-cohort models separately to upper and lower triangles.

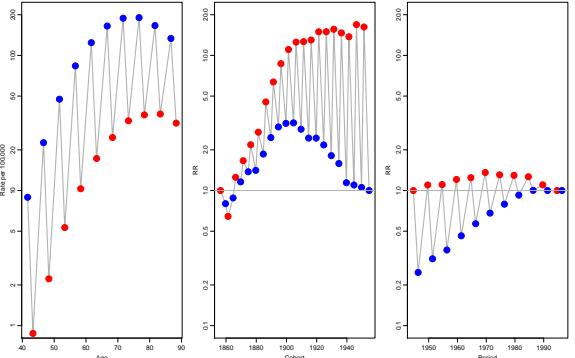

APC-model for triangular data (APC-tri)

202 / 332

APC-model for triangular data (APC-tri)

203 / 332

APC-model for triangular data (APC-tri)

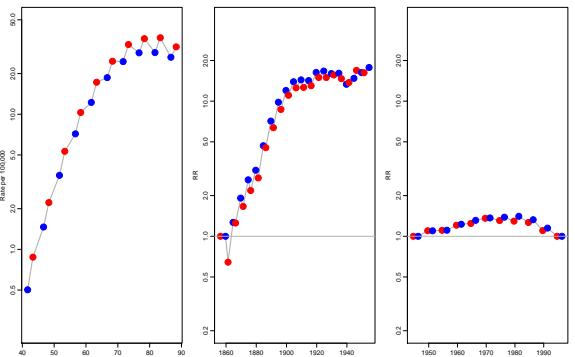

204 / 332

Now, explicitly fit models for upper and lower triangles:

```
> mx.u <- glm( D ~ factor(Ax) - 1 +
+   factor(Cx) +
+   factor(Px) + offset( log( Y/10^5 ) ), family=poisson,
+   data=lungDK[lungDK$up==1,])
> mx.l <- glm( D ~ factor(Ax) - 1 +
+   factor(Cx) +
+   factor(Px) + offset( log( Y/10^5 ) ), family=poisson,
+   data=lungDK[lungDK$up==0,])
> mx$deviance
[1] 284.7269
> mx.l$deviance
[1] 134.4566
> mx.u$deviance
[1] 150.2703
> mx.l$deviance+mx.u$deviance
[1] 284.7269
```

APC-model for triangular data (APC-tri)

205 / 332

APC-model for triangular data (APC-tri)

206 / 332

Modeling for Lexis triangles

- Modeling by factors not possible
- Two separate models that cannot be fitted together
- We are not using the **quantitative** values of age, period and cohort.
- Solution:** parametric models using the quantitative nature of a , p and $c = p - a$.
- ...so we need to handle smooth parametric functions.

APC-model for triangular data (APC-tri)

Non-linear effects (crv-mod)

221 / 332

Age and period effect

Non-linear effects (crv-mod)

225 / 332

Age and period effect with ci.exp

- In rate models there is always one term with the **rate** dimension.
- Usually **age**
- But it must refer to specific **reference** values for **all other** variables (in this case only P).
- For the “other” variables, report the RR **relative** to the reference point.
- Only parameters relevant for the variable (P) actually used in the calculation.
- We are computing the difference between two predictions.
- ... as well as the confidence intervals for it.

Non-linear effects (crv-mod)

226 / 332

$$\log(\lambda(a, p)) = f(a) + g(p) + h(c)$$

Possible choices for non-linear parametric functions describing the effect of the three **quantitative** variables:

- Polynomials / fractional polynomials.
- Linear / quadratic / cubic splines.
- Natural splines.

All of these contain the linear effect as special case.

APC-model: Parametrization (APC-par)

229 / 332

APC-model: Parametrization

Bendix Carstensen

Statistical Analysis in the Lexis Diagram:

Age-Period-Cohort models

— and some cousins

European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

APC-par

What's the problem?

- One parameter is assigned to each distinct value of the timescales, the **scale** of the variables is not used.
- The solution is to “tie together” the points on the scales together with smooth functions of the **mean** age, period and cohort with three functions:

$$\lambda_{ap} = f(a) + g(p) + h(c)$$

- The practical problem is how to choose a reasonable parametrization of these functions, and how to get estimates.

APC-model: Parametrization (APC-par)

227 / 332

Smooth functions

Possible choices for non-linear parametric functions describing the effect of the three **quantitative** variables:

- Polynomials / fractional polynomials.
- Linear / quadratic / cubic splines.
- Natural splines.

All of these contain the linear effect as special case.

APC-model: Parametrization (APC-par)

229 / 332

Parametrization of effects

There are still three “free” parameters:

$$\tilde{f}(a) = f(a) - \mu_a - \gamma a$$

$$\tilde{g}(p) = g(p) + \mu_a + \mu_c + \gamma p$$

$$\tilde{h}(c) = h(c) - \mu_c - \gamma c$$

Any set of 3 numbers, μ_a , μ_c and γ will produce effects with the same sum:

$$\tilde{f}(a) + \tilde{g}(p) + \tilde{h}(c) = f(a) + g(p) + h(c)$$

The problem is to choose μ_a , μ_c and γ according to some criterion for the functions.

APC-model: Parametrization (APC-par)

230 / 332

Parametrization principle

- The age-function should be interpretable as log age-specific rates in a cohort c_0 after adjustment for the period effect.
- The cohort function is 0 at a reference cohort c_0 , interpretable as log-RR relative to cohort c_0 .
- The period function is 0 on average with 0 slope, interpretable as log-RR relative to the age-cohort prediction. (residual log-RR).

This will yield cohort age-effects a.k.a. **longitudinal** age effects.

Biologically interpretable:

— what happens during the lifespan of a cohort?

APC-model: Parametrization (APC-par)

231 / 332

The identifiability problem still exists:

$$c = p - a \Leftrightarrow p - a - c = 0$$

$$\begin{aligned}\lambda_{ap} &= f(a) + g(p) + h(c) \\ &= f(a) + g(p) + h(c) + \gamma(p - a - c) \\ &= f(a) - \mu_a - \gamma a + \\ &\quad g(p) + \mu_a + \mu_c + \gamma p + \\ &\quad h(c) - \mu_c - \gamma c\end{aligned}$$

A decision on parametrization is needed.
... it must be **external to the model**.

APC-model: Parametrization (APC-par)

228 / 332

Period-major parametrization

- Alternatively, the period function could be constrained to be 0 at a reference date, p_0 .
- Then, age-effects at $a_0 = p_0 - c_0$ would equal the fitted rate for period p_0 (and cohort c_0), and the period effects would be residual log-RRs relative to p_0 .
- Gives period or **cross-sectional** age-effects
- Bureaucratically interpretable:
— what was seen at a particular date?

APC-model: Parametrization (APC-par)

232 / 332

Implementation:

1. Obtain any set of parameters $f(a)$, $g(p)$, $h(c)$.
2. Extract the trend from the period effect (find μ and β):

$$\tilde{g}(p) = \hat{g}(p) - (\mu + \beta p)$$
3. Decide on a reference cohort c_0 .
4. Use the functions:

$$\begin{aligned}\tilde{f}(a) &= \hat{f}(a) + \mu + \beta a + \hat{h}(c_0) + \beta c_0 \\ \tilde{g}(p) &= \hat{g}(p) - \mu - \beta p \\ \tilde{h}(c) &= \hat{h}(c) + \beta c - \hat{h}(c_0) - \beta c_0\end{aligned}$$

APC-model: Parametrization (APC-par)

233/ 332

"Extract the trend"

- ▶ Not a well-defined concept:
 - ▶ Regress $\hat{g}(p)$ on p for all units in the dataset.
 - ▶ Regress $\hat{g}(p)$ on p for all different values of p .
 - ▶ Weighted regression — what weights?
- ▶ How do we get the standard errors?
- ▶ Matrix-algebra!
- ▶ Projections!
- ▶ Weighted inner product...

APC-model: Parametrization (APC-par)

234/ 332

Parametric function

Suppose that $g(p)$ is parametrized using the design matrix \mathbf{M} , with the estimated parameters π .

Example: 2nd degree polynomial:

$$\mathbf{M} = \begin{bmatrix} 1 & p_1 & p_1^2 \\ 1 & p_2 & p_2^2 \\ \vdots & \vdots & \vdots \\ 1 & p_n & p_n^2 \end{bmatrix} \quad \pi = \begin{bmatrix} \pi_0 \\ \pi_1 \\ \pi_2 \end{bmatrix} \quad g(p) = \mathbf{M}\pi$$

`nrow(M)` is the no. of observations in the dataset,

`ncol(M)` is the no. of parameters

APC-model: Parametrization (APC-par)

235/ 332

Extract the trend from g :

Vectors \mathbf{x} and \mathbf{y} are orthogonal if the inner product is 0

$$\mathbf{x} \perp \mathbf{y} \Leftrightarrow \langle \mathbf{x} | \mathbf{y} \rangle = \sum_i x_i y_i = 0$$

- ▶ $\langle \tilde{g}(p) | 1 \rangle = 0$, $\langle \tilde{g}(p) | p \rangle = 0$, i.e. \tilde{g} is **orthogonal** to $[1:p]$.
- ▶ Suppose $\tilde{g}(p) = \tilde{\mathbf{M}}\pi$, then for **any** parameter vector π :

$$\langle \tilde{\mathbf{M}}\pi | 1 \rangle = 0, \quad \langle \tilde{\mathbf{M}}\pi | p \rangle = 0 \implies \tilde{\mathbf{M}} \perp [1:p]$$
- ▶ Thus we just need to be able to produce $\tilde{\mathbf{M}}$ from \mathbf{M} :
 Projection on the orthogonal complement of $\text{span}([1:p])$.
- ▶ **But:** orthogonality requires an inner product!

APC-model: Parametrization (APC-par)

236/ 332

Practical parametrization

1. Set up model matrices for age, period and cohort, M_a , M_p and M_c . Intercept in all three.
2. Extract the linear trend from M_p and M_c , by projecting their columns onto the orthogonal complement of $[1:p]$ and $[1:c]$, respectively
3. Center the cohort effect around c_0 :

Take a row from \tilde{M}_c corresponding to c_0 , replicate to dimension as \tilde{M}_c , and subtract it from \tilde{M}_c to form \tilde{M}_{c_0} .

APC-model: Parametrization (APC-par)

237/ 332

4. Use:

M_a for the age-effects,
 M_p for the period effects and
 $[c - c_0; \tilde{M}_{c_0}]$ for the cohort effects.

5. Value of $\hat{f}(a)$ is $M_a \hat{\beta}_a$, similarly for the other two effects.
 Variance is found by $M_a' \hat{\Sigma}_a M_a$, where $\hat{\Sigma}_a$ is the variance-covariance matrix of $\hat{\beta}_a$.

APC-model: Parametrization (APC-par)

238/ 332

Information about a parameter in the data

Information about log-rate $\theta = \log(\lambda)$:

$$l(\theta | D, Y) = D\theta - e^\theta Y, \quad l'_\theta = D - e^\theta Y, \quad l''_\theta = -e^\theta Y$$

$$\text{so } I(\hat{\theta}) = e^{\hat{\theta}} Y = \hat{\lambda} Y = D.$$

Information about square root of rate $\sigma = \sqrt{\lambda}$:

$$l(\sigma | D, Y) = D \log(\sigma^2) - \sigma^2 Y, \quad l'_\sigma = (D/\sigma^2) 2\sigma - 2\sigma Y = 2D/\sigma - 2\sigma Y$$

$$\text{so } I(\hat{\sigma}) = -2D/\hat{\sigma}^2 - 2Y = -4Y$$

APC-model: Parametrization (APC-par)

239/ 332

Information in the data and inner product

- ▶ Inner products:

$$\langle \mathbf{m}_j | \mathbf{m}_k \rangle = \sum_i m_{ij} m_{ik} \quad \langle \mathbf{m}_j | \mathbf{m}_k \rangle = \sum_i m_{ij} w_i m_{ik}$$

- ▶ Weights could be chosen as:

- ▶ $w_i = Y_i$, i.e. proportional to the information content for $\sigma = \sqrt{\lambda}$,
 $\text{dr.extr} = \text{Y}$ (the default)
- ▶ $w_i = D_i$, i.e. proportional to the information content for $\theta = \log(\lambda)$,
 $\text{dr.extr} \in \text{c(D, T)}$
- ▶ $w_i = Y_i^2/D_i$, i.e. proportional to the information content for λ ,
 $\text{dr.extr} \in \text{c(L, R)}$
- ▶ $w_i = 1$, the "usual" inner product — implicitly used in most of the literature — any other (character) value for dr.extr .

APC-model: Parametrization (APC-par)

Substantial differences between the estimated drifts.

APC-model: Parametrization (APC-par)

251 / 332

Parametrization of the APC model is arbitrary

- ▶ Separation of the three effects relies on arbitrary principles, e.g.:
 - ▶ Age is the primary effect
 - ▶ Cohort the secondary, reference c_0
 - ▶ Period is the residual
 - ▶ Inner product for trend extraction
- ▶ There is no magical fix that allows you to escape this, it comes from modelling a , p and $p - a$
- ▶ Any fix has some (hidden) assumption(s)
- ▶ ... but the **fitted values** are the same

APC-model: Parametrization (APC-par)

253 / 332

LeeCarter

Lee-Carter model for (mortality) rates

Lee & Carter, JASA, 1992:

$$\log(\lambda_{x,t}) = a_x + b_x \times k_t$$

x is age; t is calendar time

- ▶ Formulated originally using as step-functions with one parameter per age/period.
- ▶ Implicitly assumes a data lay out by age and period:
A, B or C-sets, but **not** Lexis triangles
- ▶ Using Lexis triangles with categorical set-up would just produce separate models for upper and lower triangles.

Lee-Carter model (LeeCarter)

254 / 332

Lee-Carter model in continuous time

For **any** set of subsets of a Lexis diagram:

$$\log(\lambda(a, t)) = f(a) + b(a) \times k(t)$$

- ▶ $f(a)$, $b(a)$ smooth functions of age, a is **quantitative**
- ▶ $k(t)$ smooth function of period, t is **quantitative**
- ▶ Relative **scaling** of $b(a)$ and $k(t)$ cannot be determined
- ▶ $k(t)$ only determined up to an **affine** transformation:

$$\begin{aligned} f(a) + b(a)k(t) &= f(a) + (b(a)/n)(m + k(t) \times n) \\ &\quad - (b(a)/n) \times m \\ &= \tilde{f}(a) + \tilde{b}(a)\tilde{k}(t) \end{aligned}$$

Lee-Carter model (LeeCarter)

255 / 332

APC-model: Parametrization (APC-par)

252 / 332

Lee-Carter model in continuous time

$$\log(\lambda(a, t)) = f(a) + b(a) \times k(t)$$

- ▶ Lee-Carter model is an extension of the age-period model; if $b(a) = 1$ it is the age-period model.
 - ▶ The extension is an age×period interaction, but not a traditional one:
- $$\log(\lambda(a, t)) = f(a) + b(a) \times k(t) = f(a) + k(t) + (b(a) - 1) \times k(t)$$
- ▶ Main effect and interaction component of t are constrained to be identical.

Lee-Carter model (LeeCarter)

256 / 332

Main effect and interaction term

Main effect and interaction component of t are constrained to be identical.

None of these are Lee-Carter models:

```
> glm( D ~ Ns(A, kn=a1.kn) + Ns(A, kn=a2.kn, i=T):Ns(P, kn=p.kn), ... )
> glm( D ~ Ns(A, kn=a1.kn) + Ns(A, kn=a2.kn, i=T)*Ns(P, kn=p.kn), ... )
> glm( D ~ Ns(A, kn=a1.kn) + Ns(P, kn=p.kn) + Ns(A, kn=a2.kn, i=T):Ns(P, kn=p.kn), ... )
```

Lee-Carter model (LeeCarter)

257 / 332

Lee-Carter model interpretation

$$\log(\lambda(a, p)) = f(a) + b(a) \times k(p)$$

- ▶ Constraints:
 - $f(a)$ is the basic age-specific mortality
 - $k(p)$ is the rate-ratio (RR) as a function of p :
 - relative to p_{ref} where $k(p_{ref}) = 1$
 - for persons aged a_{ref} where $b(a_{ref}) = 1$
- ▶ $b(a)$ is an age-specific multiplier for the RR $k(p)$
- ▶ Choose p_{ref} and a_{ref} a priori.

Lee-Carter model (LeeCarter)

258 / 332

> abline(h=1)
> matplot(dmg.lcM$year, (dmg.lcM$kt-20)/50,
+   ylab="Time effect",
+   xlab="Date", type="l", lty=1, lwd=4)
> abline(h=0)
```

Lee-Carter model (LeeCarter)

264 / 332

Lee-Carter with demography rescaled

Lee-Carter model (LeeCarter)

265 / 332

Lee-Carter with ilc

- The `lca.rh` function fits the model using maximum likelihood (proportional scaling)
 - Fits the more general model and submodels of it:
- $$\log(\lambda(a, p)) = f(a) + b(a) \times k(p) + c(a)m(p - a)$$
- Age interaction with between age and both period and/or cohort (=period-age)
 - It is also an extension of the APC-model; if $b(a) = 1$ and $c(a) = 1$ it's the APC-model.
 - ⇒ suffers from the same identifiability problem

Lee-Carter model (LeeCarter)

266 / 332

Lee-Carter with ilc I

```
> library(ilc)
> ilc.lcM <- lca.rh(mrt(lcM), model="lc", interpolate=TRUE, verbose=FALSE)

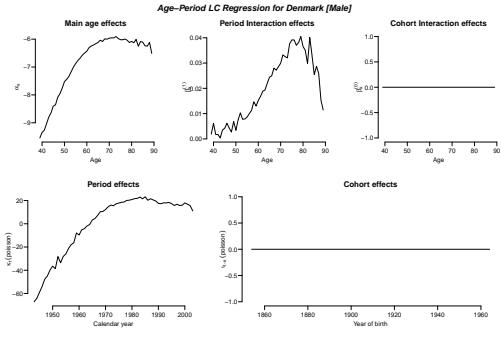

Original sample: Mortality data for Denmark
Series: Male
Years: 1943 - 2003
Ages: 39 - 89
Applied sample: Mortality data for Denmark (Corrected: interpolate)
Series: Male
Years: 1943 - 2003
Ages: 39 - 89

Fitting model: [ LC = a(x)+b1(x)*k(t) ]
- with poisson error structure and with deaths as weights -
Iterations finished in: 34 steps
> plot(ilc.lcM)
```

APC-models for several datasets (APC2)

289 / 332

Several datasets I

- Separate models for each
- Rate-ratios between two sets of fitted rates also follow an APC model
- Constraints does not necessarily carry over to RRs
- Test for equality of effects: non-linear and linear
- Take care not to violate the **principle of marginality**: — do not test linear terms when non-linear terms are in the model.

APC-model: Interactions (APC-int)

303 / 332

- ... but these are not the estimates we really want as before.
- The detrended estimates are not available from the fitted values, because the parametrization they rely on is a function of **data**.
- Of course the parameters can be extracted but it requires a construction of the model matrices as we did first
- How is shown in the section “Reparametrizations” in the notes on “Introductory linear algebra with R”.

APC-model: Interactions (APC-int)

APC-model: Interactions (APC-int)

304 / 332

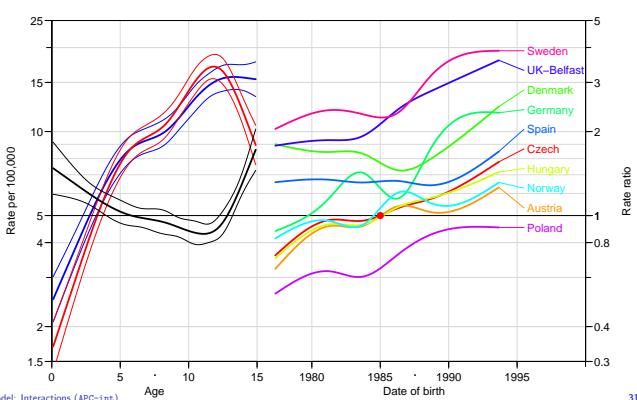

308 / 332

APC-model: Interactions (APC-int)

309 / 332

APC-model: Interactions (APC-int)

310 / 332

Identifiability

Predictions based in the three functions $(f(a), g(p)$ and $h(c)$ must give the same prediction also for the reparametrized version:

$$\begin{aligned}\log(\lambda(a, p)) &= \tilde{f}(a) + \tilde{g}(p) + \tilde{h}(c) \\ &= (f(a) - \gamma a) + \\ &\quad (g(p) + \gamma p) + \\ &\quad (h(c) - \gamma c)\end{aligned}$$

A prediction based on the parametrization $(f(a), g(p), h(c))$ must give the same predictions as one based on $(\tilde{f}(a), \tilde{g}(p), \tilde{h}(c))$

Predicting future rates (predict)

312 / 332

Parametrization invariance

- Prediction of the future course of g and h must preserve addition of a linear term in the argument:

$$\begin{aligned}\text{pred}(g(p) + \gamma p) &= \text{pred}(g(p)) + \gamma p \\ \text{pred}(h(c) - \gamma c) &= \text{pred}(h(c)) - \gamma c\end{aligned}$$
- If this is met, the predictions made will not depend on the parametrization chosen.
- If one of the conditions does not hold, the prediction will depend on the parametrization chosen.
- Any linear combination of (known) function values of $g(p)$ and $h(c)$ will work.

Predicting future rates (predict)

313 / 332

Predicting future rates

Bendix Carstensen

Statistical Analysis in the Lexis Diagram:
Age-Period-Cohort models

— and some cousins
European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

predict

Identifiability

- Any linear combination of function values of $g(p)$ and $h(c)$ will work.
- Coefficients in the linear combinations used for g and h must be the same; otherwise the prediction will depend on the specific parametrization.
- What works best in reality is difficult to say:
depends on the subject matter.

Predicting future rates (predict)

314 / 332

Prediction of future rates

Model:

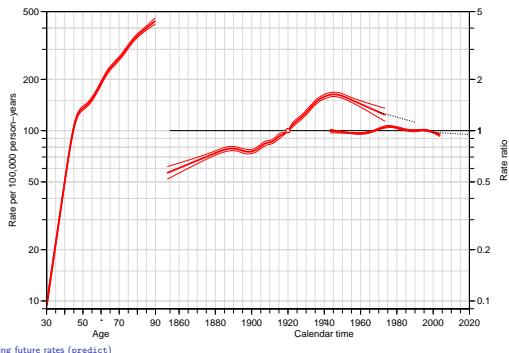

$$\log(\lambda(a, p)) = f(a) + g(p) + h(c)$$

- Why not just extend the estimated functions into the future?
- Natural splines lend themselves easily to this [?]
- The parametrization curse — the model as stated is not uniquely parametrized.
- Predictions from the model must be invariant under reparametrization.

Predicting future rates (predict)

311 / 332

Example: Breast cancer in Denmark

315 / 332

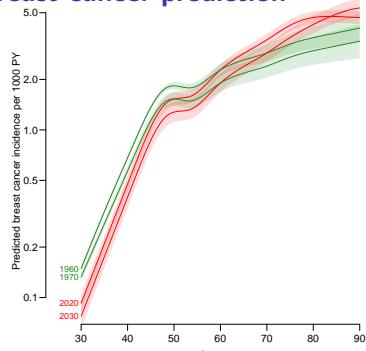

Practicalities

- ▶ Long term predictions notoriously unstable.
- ▶ Decreasing slopes are possible, the requirement is that at any future point changes in the parametrization should cancel out in the predictions.

Predicting future rates (predict)

316 / 332

Breast cancer prediction

317 / 332

APC-model for quantitative outcomes

- ▶ Model:
- $\text{BMI}_i = f(a(i)) + g(p(i)) + h(p(i) - a(i)) + e_i, \quad e_i \sim \mathcal{N}(0, \sigma^2)$
- ▶ But the identification problem is still the same:
- $c(i) = p(i) - a(i), \quad \forall i$
- ▶ But the same machinery applies with extraction of the effects
- and plotting of predictions of
 - ▶ $E(\text{BMI})$
 - ▶ quantiles of BMI

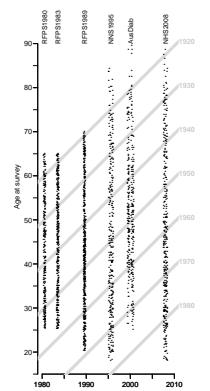

Continuous outcomes (cont.)

319 / 332

APC-model for quantitative outcomes

- ▶ Australian surveys
- ▶ 40,000+ person surveyed at different times
- ▶ Date of birth, data of survey, sex and BMI known.
- ▶ How does BMI evolve **in the population?**
- ▶ Linear model ($E(\text{BMI})$)
- ▶ Quantile regression (median, quantile)
- the latter is not a model

Continuous outcomes (cont.)

320 / 332

Continuous outcomes

Age-Period-Cohort models
— and some cousins
European Doctoral School of Demography, Odense, April 2019

<http://BendixCarstensen/APC/EDSD-2019>

cont

Continuous outcomes (cont.)

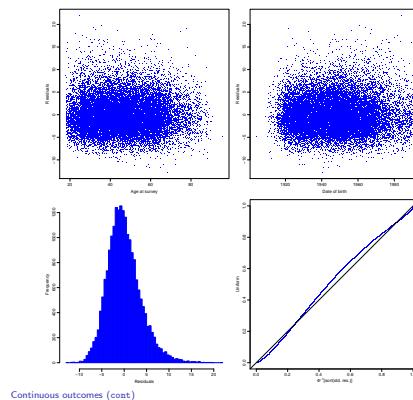

321 / 332

APC-model for quantitative outcomes

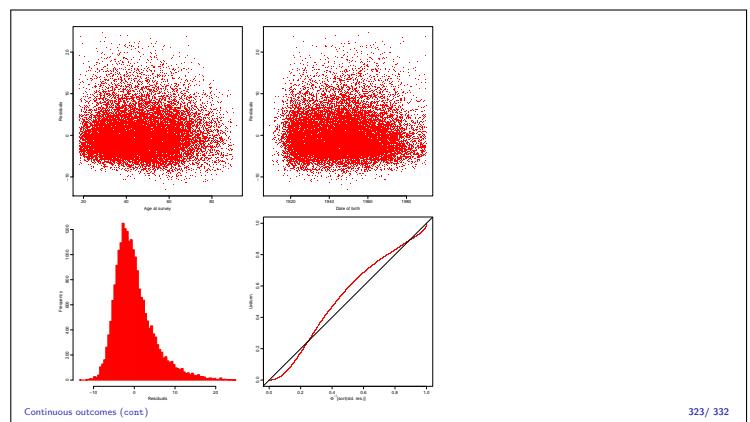

- ▶ The classical model is:
- $\log(\lambda(a, p)) = f(a) + g(p) + h(p - a)$
- ▶ In principle it would be possible to use an identity-link model:
- $\lambda(a, p) = f(a) + g(p) + h(p - a)$
- ▶ ... or use APC-modelling for **measurement** data such as BMI, measured at different times and ages:
- $\text{BMI}_{ap} = f(a) + g(p) + h(p - a) + e_{ap}, \quad e_i \sim \mathcal{N}(0, \sigma^2)$
- ▶ ... or more precisely:
- $\text{BMI}_i = f(a(i)) + g(p(i)) + h(p(i) - a(i)) + e_i, \quad e_i \sim \mathcal{N}(0, \sigma^2)$
