Haukeland University Hospital, Bergen, Norway
19–20 March 2014

<http://BendixCarstensen.com/MethComp/Courses/Bergen.2014>

What this is about

- ▶ Two (laboratory) methods for measuring the same clinical quantity.
- ▶ Persons are measured with both methods.
- ▶ Scaled measurements (continuous).
- ▶ Errors in both variables.

1 / 144

Glucose measurements

2 / 144

Course outlook

- ▶ **Model** based approach
- ▶ Explicit **parametric** models:
 - ▶ Assumptions are made clear
 - ▶ — relaxing assumptions is clear
- ▶ **Comparison** of methods:
 - can one replace the other?
- ▶ **Conversion** between methods:
 - if measurement is y_1 with method 1, what would it be with method 2?
- ▶ Examples from [MethComp](#) package for **R**.
- ▶ Code and output included on the slides
- ▶ — and on the course web-site.

3 / 144

Order of topics 19-20 March

- ▶ Wednesday 19th
 - ▶ One measurement by each method
 - ▶ Computing
 - ▶ Linear bias between methods
 - ▶ Variable SD
 - ▶ Practical milk, plvol
 - ▶ Replicate measurements, exchangeable / linked
 - ▶ Practical fat, sbp2
 - ▶ Repeatability, reproducibility
 - ▶ Coefficient of variation
- ▶ Thursday 20th
 - ▶ Replicate measurements and linear bias
 - ▶ Practical ox 1–8
 - ▶ Converting between methods
 - ▶ MCMC methods for estimation of variance components
 - ▶ Practical ox 9–

4 / 144

Comparing two methods with one measurement on each

Bendix Carstensen

19–20 March 2014

Haukeland University Hospital, Bergen, Norway

<http://BendixCarstensen.com/MethComp/Courses/Bergen.2014>

(Comp-simple)

Comparing measurement methods

General questions:

- ▶ Are results systematically different?
- ▶ Can one method safely be replaced by another?
- ▶ What is the size of measurement errors?
- ▶ Different centres use different methods of measurement: How can we convert from one method to another?
- ▶ How precise is the conversion?

Comparing two methods with one measurement on each (Comp-simple)

5 / 144

Fat content in human milk:

The relationship looks like:

$$y_1 = a + by_2$$

Comparing two methods with one measurement on each (Comp-simple)

6 / 144

```
> library(MethComp)
> # sessionInfo()
> data( milk )
> milk <- Meth( milk )

The following variables from the dataframe
"milk" are used as the Meth variables:
meth: meth
item: item
y: y
#Replicates
Method      1 #Items #Obs: 90 Values: min med max
Gerber      45   45   45   0.85 2.67 6.20
Trig        45   45   45   0.96 2.67 6.21

> par( mar=c(3,3,1,1),mgp=c(3,1,0)/1.6 )
> BA.plot( milk, pl.type="comp", col.line="transparent",
+         lwd=c(3,0,0), axlim=c(1,6)-0.1 )
> abline(0,1)
```

Comparing two methods with one measurement on each (Comp-simple)

7 / 144

Two methods — one measurement by each

- ▶ How large is the difference between a measurement with method 1 and one with method 2 on a (randomly chosen) person?

$$D_i = y_{2i} - y_{1i}, \quad \bar{D}, \quad \text{s.d.}(D)$$

- ▶ 95% prediction interval for the difference between a measurement by method 1 and one by method 2. [1, 2]
- ▶ **Limits of agreement:**

$$\bar{D} \pm 2 \times \text{s.d.}(D)$$

Limits of agreement: Interpretation

- ▶ If a new patient is measured **once** with each of the two methods, the difference between the two values will with 95% probability be within the limits of agreement.
- ▶ This is a **prediction** interval for a single (future) difference.
- ▶ Interpretation requires a **clinical** input: Are the limits of agreement sufficiently narrow to make the use of either of the methods clinically acceptable?
- ▶ Is it relevant to test if the mean is 0?

Limits of agreement: Test? **No!**

Testing whether the difference is 0 is a bad idea:

- ▶ Small study: Null accepted even if the difference is important.
- ▶ Large study: Null rejected even if the difference is clinically irrelevant.
- ▶ It is an **equivalence** problem:
 1. How small can we reasonably safely assume the differences to be?
 2. **Testing is irrelevant:** — not interesting if the **mean** difference is significantly different from 0.
 3. **Clinical input is required** to interpret the **prediction** interval.

Limits of agreement:

Plot differences (D_i) versus averages (A_i).

Comparing two methods with one measurement on each (Comp-simple)

11 / 144

```
> par( mar=c(3,3,1,3), mgp=c(3,1,0)/1.6 )  
> BA.plot( milk, diflim=c(-0.5,0.5), grid=FALSE )
```

Comparing two methods with one measurement on each (Comp-simple)

12 / 144

Model behind “Limits of agreement”

- ▶ Methods $m = 1, \dots, M$, applied to $i = 1, \dots, I$ individuals:

$$y_{mi} = \alpha_m + \mu_i + e_{mi}$$

$$e_{mi} \sim \mathcal{N}(0, \sigma_m^2) \quad \text{measurement error}$$

- ▶ Two-way analysis of variance model, with **different** variances in columns.
- ▶ Different variances are not identifiable without replicate measurements for $M = 2$.

The variances σ_m are based on the distance of the obs to the mean across methods, but they are always numerically identical with only 2 methods.

Limits of agreement:

- Usually interpreted as the likely difference between two future measurements, one with each method:

$$\widehat{y_2 - y_1} = \hat{D} = \alpha_2 - \alpha_1 \pm 2 \text{s.d.}(D)$$

- Convert to prediction interval for y_2 given y_1 :

$$\hat{y}_{2|1} = \hat{y}_2|y_1 = \alpha_2 - \alpha_1 + y_1 \pm 2 \text{s.d.}(D)$$

- Formally, we should replace:

$$2 \rightarrow t_{0.975}^{(I-1)} \sqrt{1 + 1/I}$$

which equals 2 for $I = 85$ and 1.96 for $I = \infty$

Models

14 / 144

Spurious correlation?

Different variances induce correlation between D_i and $A_i = (y_{1i} + y_{2i})/2$, if the variances of y_{1i} and y_{2i} are ζ_1^2 and ζ_2^2 respectively:

$$\text{cov}(D_i, A_i) = \frac{1}{2}(\zeta_2^2 - \zeta_1^2) \neq 0 \quad \text{if } \zeta_1 \neq \zeta_2$$

In correlation terms:

$$\rho(D, A) = \frac{1}{2} \left(\frac{\zeta_2^2 - \zeta_1^2}{\zeta_1^2 + \zeta_2^2} \right)$$

i.e. the correlation depends on whether the difference between the variances is large relative to the sizes of the two.

Models

15 / 144

... not really...

The variances we were using were the **marginal** variances of y_1 and y_2 :

$$y_{mi} = \alpha_m + \mu_i + e_{mi}$$
$$\text{var}(y_m) = \text{var}(\mu_i) + \sigma_m^2$$

and hence the correlation expression is:

$$\rho(D, A) = \frac{1}{2} \left(\frac{\zeta_2^2 - \zeta_1^2}{\zeta_1^2 + \zeta_2^2} \right) = \frac{1}{2} \left(\frac{\sigma_2^2 - \sigma_1^2}{2\text{var}(\mu_i) + \sigma_1^2 + \sigma_2^2} \right)$$

Hence only relevant if $\text{var}(\mu_i)$ is small relative to σ_1^2 and σ_2^2 .

Not likely in practise — the μ s are normally chosen to be widely spread, so $\text{var}(\mu_i) \gg \sigma_1^2, \sigma_2^2$

Models

Introduction to computing

Bendix Carstensen

SAoMCS

19–20 March 2014

Haukeland University Hospital, Bergen, Norway

<http://BendixCarstensen.com/MethComp/Courses/Bergen.2014>

(Intro-comp)

Course structure

The course is both theoretical and practical, i.e. the aim is to convey a basic understanding of the problems in method comparison studies, but also to convey practical skills in handling the statistical analysis.

- ▶ **R** for data manipulation and graphics.
- ▶ Occasionally BUGS (JAGS) for estimation in non-linear variance component models.

How it works

Example data sets are included in the MethComp package.

Functions in MethComp are based on a data frame with a particular structure; a `Meth` object:

```
meth — method (factor)
item — item, person, individual, sample (factor)
repl — replicate (if present) (factor)
  y — the actual measurement (numerical)
```

Once converted to a Meth object, just use `summary`, `plot` etc.

How it looks I

```
> library( MethComp )
> data( ox )
> ox <- Meth( ox )

The following variables from the dataframe
"ox" are used as the Meth variables:
meth: meth
item: item
repl: repl
y: y
  #Replicates
Method  1  2  3 #Items #Obs: 354 Values: min med max
CO      1  4 56   61   177   22.2 78.6 93.5
pulse  1  4 56   61   177   24.0 75.0 94.0

> ( subset( ox, as.integer(item)<3 ) )
```

How it looks II

```
      meth item repl   y
1      CO    1    1 78.0
2      CO    1    2 76.4
3      CO    1    3 77.2
4      CO    2    1 68.7
5      CO    2    2 67.6
6      CO    2    3 68.3
7 pulse    1    1 71.0
8 pulse    1    2 72.0
9 pulse    1    3 73.0
10 pulse   2    1 68.0
11 pulse   2    2 67.0
12 pulse   2    3 68.0

> subset( to.wide(ox), as.integer(item)<3 )

      item repl   CO pulse
1      1    1 78.0   71
2      1    2 76.4   72
3      1    3 77.2   73
4      2    1 68.7   68
5      2    2 67.6   67
6      2    3 68.3   68
```

Analyses in this course

- ▶ Scatter plots.
- ▶ Bland-Altman plots ($(y_2 - y_1)$ vs. $(y_1 + y_2)/2$)
- ▶ Limits of agreement.
- ▶ Models with constant bias.
- ▶ Models with linear bias.
- ▶ Conversion formulae between methods.
- ▶ Plots of conversion equations.
- ▶ Reporting of variance components.
- ▶ Transformation of response.

Data objects in MethComp

- ▶ `Meth` Dataframe in the “long” format, with predefined variable names.
- ▶ `MethComp` Results from an analysis with estimated conversions between methods and (if applicable) variance components. Produced by different functions.
- ▶ `MCmcmc` Results from a MCMC analysis of a model. Can be converted to a `MethComp` object.

Functions in the MethComp package

5 broad categories of functions in MethComp:

- ▶ Data manipulation — reshaping and changing data.
- ▶ Graphical — exploring data.
- ▶ Simulation — generating datasets or replacing variables.
- ▶ Analysis functions — fitting models to data.
- ▶ Reporting functions — displaying the results from analyses.

Data manipulation functions

- ▶ `Meth` Sets up a `Meth` object — a dataframe in the “long” format, with predefined variable names.
- ▶ `make.repl` Generates a `repl` column in a data frame with columns `meth`, `item` and `y`.
- ▶ `perm.repl` Randomly permutes replicates within (method,item) and assigns new replicate numbers.
- ▶ `to.wide/to.long` Transforms a data frame in the long form to the wide form and vice versa.
- ▶ `Meth.sim` Simulates a dataset (a `Meth` object) from a method comparison experiment.

Graphical functions (basic)

- ▶ `plot.Meth` Plots all methods against all other, both as a scatter plot and as a Bland-Altman plot.
- ▶ `BA.plot` Makes a Bland-Altman plot of two methods from a data frame with method comparison data, and computes limits of agreement.
- ▶ `bothlines` Adds regression lines of y on x and vice versa to a scatter plot.

Analysis functions (simple)

- ▶ `DA.reg`, regresses the differences on the averages. Also regresses the absolute residuals on the averages to check whether the variance is constant. Returns a `MethComp` object.
- ▶ `BA.est` Estimates in the variance components models underlying the concept of limits of agreement, and returns the bias and the variance components. Assumes constant bias between methods. Returns a `MethComp` object.
- ▶ `VC.est` The workhorse behind `BA.est`.
- ▶ `Deming` Performs Deming regression, i.e. regression with errors in both variables.

Analysis functions (general)

- ▶ `MCmcmc` Estimates via BUGS (JAGS) in the general model with non-constant bias. Produces an `MCmcmc` object. Which can be converted to a `MethComp` object.
- ▶ `AltReg` Estimates via ad-hoc procedure (alternating regressions) in a model with linear bias between methods. Returns a matrix of estimates with the conversion parameters as well as the variance components. Returns a `MethComp` object.

Reporting functions

- ▶ `print.MethComp` Prints a table of conversion equations based on an estimated model.
- ▶ `plot.MethComp` Graphs the estimated relationship between methods based on an estimated model.
- ▶ `print.MCmcmc` Table of conversion equations between methods analyzed.
- ▶ `plot.MCmcmc` Conversion lines between methods with prediction limits.
- ▶ `post.MCmcmc` Smoothed posteriors of estimates.
- ▶ `trace.MCmcmc` Simulation traces from an MCmcmc object.

Does it work? I

You should get something reasonable out of this:

```
> library( MethComp )
> data( ox )
> ox <- Meth( ox )
> summary( ox )
> plot( ox )
> BA.plot( ox )
> BA.est( ox )
> ( AR.ox <- AltReg(ox,linked=TRUE,trace=TRUE) )
> MCmcmc( ox, code.only=TRUE )
> MC.ox <- MCmcmc( ox, n.iter=500 )
> print( MC.ox )
> plot( MC.ox )
> trace.MCmcmc( MC.ox )
> post.MCmcmc( MC.ox )
```

Non-constant difference

Bendix Carstensen

SAoMCS

19–20 March 2014

Haukeland University Hospital, Bergen, Norway

<http://BendixCarstensen.com/MethComp/Courses/Bergen.2014>

(Non-const)

Limits of agreement — assumptions

- ▶ The difference between methods is constant
- ▶ The variances of the methods (and hence of the difference) is constant
- ▶ “Constant” means constant across the range of measurement values

Check this by:

- ▶ Regress differences on averages.
- ▶ Regress absolute residuals from this on the averages.

Non-constant difference (Non-const)

30/ 144

Glucose measurements

Non-constant difference (Non-const)

31/ 144

```
> options( width=61 )
> library(MethComp)
> data( glucose )
> gluc <-subset( glucose, type %in% levels(type)[c(2,4)] &
+ meth %in% c("h.cap","o.cap","n.plas1"),
+ select=c(2,3,4,6) )
> str( gluc )

'data.frame': 472 obs. of 4 variables:
 $ type: Factor w/ 4 levels "blood","plasma",...: 2 4 2 4 2 4 2 4 2 4 ...
 $ item: num 1 1 1 1 1 1 1 1 2 2 ...
 $ time: num 0 0 30 30 60 60 120 120 0 0 ...
 $ y : num 6.36 5.1 10.3 9.8 13.33 ...

> glu120 <- Meth( subset( gluc, time==120 ), meth="type", print=F )
> summary( glu120 )

#Replicates
Method      1 #Items #Obs: 119 Values: min med max
plasma      73   73   73   4.32 7.92 13.42
capil       46   46   46   4.20 7.45 11.80

> par( mar=c(3,3,1,1), mgp=c(3,1,0)/1.6 )
> BA.plot( glu120, wh.comp=2:1, pl.type="comp",
+ col.line="transparent" )
> abline( 0, 1 )
```

Non-constant difference (Non-const)

32/ 144

Glucose measurements

Non-constant difference (Non-const)

33/ 144

```
> par( mar=c(3,3,1,3), mgp=c(3,1,0)/1.6 )  
> BA.plot( glui20, wh.comp=2:1, pl.type="BA" )
```

Non-constant difference (Non-const)

34/ 144

Regress differences on averages

$$D_i = a + bA_i + e_i, \quad \text{var}(e_i) = \sigma_D^2$$

If b is different from 0, we could use this equation to derive LoA:

$$a + bA_i \pm 2\sigma_D$$

or convert to prediction as for LoA:

$$y_{2|1} = y_1 + a + bA_i \approx y_1 + a + by_1 = a + (1 + b)y_1$$

Exchanging methods would give:

$$y_{1|2} = -a + (1 - b)y_1$$

instead of:

$$y_{1|2} = \frac{-a}{1 + b} + \frac{1}{1 + b}y_1$$

Non-constant difference (Non-const)

35/ 144

Variable limits of agreement

Non-constant difference (Non-const)

36/ 144

```
> par( mar=c(3,3,1,3), mgp=c(3,1,0)/1.6 )
> BA.plot( glu120, dif.type="lin",wh.comp=2:1, pl.type="BA" )

> par( mar=c(3,3,1,3), mgp=c(3,1,0)/1.6 )
> BA.plot( glu120, dif.type="lin",wh.comp=2:1, pl.type="BA",
+         eqn=TRUE )
```

Relationships between methods:
capil-plasma = 2.24-0.33(capil+plasma)/2 (-1.08)
capil = 1.92+0.71plasma (0.93)
plasma = -2.69+1.40capil (1.30)

Non-constant difference (Non-const)

37/ 144

Using the regression of D on A properly

$$y_{2i} - y_{1i} = a + b(y_{1i} + y_{2i})/2 + e_i$$

$$y_{2i}(1 - b/2) = a + (1 + b/2)y_{1i} + e_i$$

$$y_{2i} = \frac{a}{1 - b/2} + \frac{1 + b/2}{1 - b/2}y_{1i} + \frac{1}{1 - b/2}e_i$$

$$y_{1i} = \frac{-a}{1 + b/2} + \frac{1 - b/2}{1 + b/2}y_{2i} + \frac{1}{1 + b/2}e_i$$

Details found in [5]

This is what comes out of the functions

`DA.reg` and `BA.plot`.

Non-constant difference (Non-const)

38/ 144

Conversion equation with prediction limits

Non-constant difference (Non-const)

39/ 144

```
> par( mar=c(3,3,1,1), mgp=c(3,1,0)/1.6 )
> BA.plot( glui20, dif.type="lin",wh.comp=2:1, pl.type="conv",
+         eqn=TRUE )
```

```
Relationships between methods:
capil-plasma = 2.24-0.33(capil+plasma)/2 (-1.08)
capil = 1.92+0.71plasma (0.93)
plasma = -2.69+1.40capil (1.30)
```

Non-constant difference (Non-const)

40/ 144

Why does this work?

The general model for the data is:

$$y_{1i} = \alpha_1 + \beta_1 \mu_i + e_{1i}, \quad e_{1i} \sim \mathcal{N}(0, \sigma_1^2)$$

$$y_{2i} = \alpha_2 + \beta_2 \mu_i + e_{2i}, \quad e_{2i} \sim \mathcal{N}(0, \sigma_2^2)$$

- ▶ Work out the prediction of y_{2i} given an observation of y_{1i} in terms of the α s and β s.
- ▶ Work out how differences relate to averages in terms of α s and β s.
- ▶ Use til to work out relationship between the (α, β) and (a, b)
- ▶ Then the prediction is as we just derived it.

Non-constant difference (Non-const)

41/ 144

So why is it wrong anyway?

Conceptually:

Once the β_m is introduced:

$$y_{mi} = \alpha_m + \beta_m \mu_i + e_{mi}$$

measurements by different methods are on different scales.

Hence it has formally no meaning to form the differences.

So why is it wrong anyway?

Statistically:

Under the correctly specified model, the induced model for the differences on the averages A_i , these contain the error terms, and so does the residuals.

So the covariate is not independent of the error terms.

Thus the assumptions behind regression are violated.

Then why use it?

- ▶ With only one observation per (method,item) there is not much else to do.
- ▶ If the slope linking the two methods (β_1/β_2) is not dramatically different from 1, the violations are not that big.
- ▶ Implemented in `BA.plot` and in `DA.reg`, which also checks the residuals.

For further details, see [5].

Limits of agreement — assumptions

- ▶ The difference between methods is constant
- ▶ The variances of the methods (and hence of the difference) is constant
- ▶ Residuals follow a normal distribution

Check this by:

- ▶ Regress differences on averages
- ▶ Regress absolute residuals from this on the averages
- ▶ ... the central limit theorem?

Non-constant difference (Non-const)

45 / 144

Regressing residuals on averages

- ▶ Residuals $\sim \mathcal{N}(0, \sigma^2)$
 \Rightarrow absolute residuals half-normal.
- ▶ Mean of standard half normal is:

$$\int_0^{\infty} x(2/\sqrt{2\pi})\exp(-x^2/2) dx = \sqrt{2/\pi}$$

- ▶ Mean of absolute residuals is $\sigma\sqrt{2/\pi}$
- ▶ Linear relationship of absolute residuals (R_i) to averages (A_i):

$$R_i = a + bA_i \quad \Leftrightarrow \quad \sigma(A) \approx a\sqrt{\pi/2} + b\sqrt{\pi/2}A$$

- ▶ Implemented in DA.reg.

Non-constant difference (Non-const)

46 / 144

```
Relationships between methods:
capil-plasma = 2.24-0.33(capil+plasma)/2 (1.14-0.02Avg.)
capil = 1.92+0.71plasma (0.96-0.01plasma)
plasma = -2.69+1.40capil (-1.40+0.02capil)
```

Non-constant difference (Non-const)

50/ 144

Variable mean and standard deviation

- ▶ 2-step procedure:
 - ▶ Regress D_i on A_i .
 - ▶ Regress R_i (absolute residuals) on A_i
- ▶ Can be done using quadratic rather than linear terms, or even splines. (Not in MethComp — yet, any takers?)
- ▶ Allows very flexible form of the relationships between differences and averages
- ▶ —and flexible form of the s.d. to the mean.
- ▶ The relationship $D \sim A$ is easily back-transformed to a relationship $y_1 \sim y_2$, with prediction intervals.
- ▶ Beware: **over-modelling!**

Non-constant difference (Non-const)

51 / 144

Comparing two methods with replicate measurements

Bendix Carstensen

SAoMCS

19–20 March 2014

Haukeland University Hospital, Bergen, Norway

<http://BendixCarstensen.com/MethComp/Courses/Bergen.2014>

(Comp-repl)

Replicate measurements on each item

Fat data; **exchangeable** replicates:

```
item repl  KL  SL
1      1  4.5  5.0
1      2  4.7  4.9
1      3  4.4  4.8
3      1  6.4  6.5
3      2  6.2  6.4
3      3  6.5  6.1
```

Oximetry data; linked replicates:

```
item repl  CO pulse
1      1  78.0   71
1      2  76.4   72
1      3  77.2   73
2      1  68.7   68
2      2  67.6   67
2      3  68.3   68
```

Comparing two methods with replicate measurements (Comp-repl)

52 / 144

Replicate measurements on each item

Fat data; exchangeable replicates:

item	repl	KL	SL
1	1	4.5	4.9
1	2	4.4	5.0
1	3	4.7	4.8
3	1	6.4	6.5
3	2	6.2	6.4
3	3	6.5	6.1

Oximetry data; **linked** replicates:

item	repl	CO	pulse
1	1	77.2	73
1	2	78.0	71
1	3	76.4	72
2	1	68.7	68
2	2	67.6	67
2	3	68.3	68

Extension of the model: exchangeable replicates

$$y_{mir} = \alpha_m + \mu_i + c_{mi} + e_{mir}$$
$$\text{s.d.}(c_{mi}) = \tau_m \quad \text{— “matrix”-effect}$$
$$\text{s.d.}(e_{mir}) = \sigma_m \quad \text{— measurement error}$$

- ▶ Replicates within (m, i) is needed to separate τ and σ .
- ▶ Even with replicates, the τ s are only estimable if $M > 2$.
- ▶ Still assumes that the difference between methods is constant.
- ▶ Assumes **exchangeability** of replicates.

Extension of the model: linked replicates

$$y_{mir} = \alpha_m + \mu_i + a_{ir} + c_{mi} + e_{mir}$$
$$\text{s.d.}(a_{ir}) = \omega \quad \text{— between replicates}$$
$$\text{s.d.}(c_{mi}) = \tau_m \quad \text{— “matrix”-effect}$$
$$\text{s.d.}(e_{mir}) = \sigma_m \quad \text{— measurement error}$$

- ▶ Still assumes difference between methods constant.
- ▶ Replicates **linked** between methods:
 a_{ir} is common across methods; first replicate on a person is made under similar conditions for all methods, second too etc.

Replicate measurements

Three approaches to LoA with replicate measurements:

1. Means over replicates within each method by item stratum.
2. Replicates within item are taken as items.
3. Fit the model and use it for the LoA:
 - ▶ The model is a standard linear mixed model with separate variances per method.
 - ▶ The model is fitted using `BA.est(data,linked=TRUE)` — later.

Oximetry data

```
> library(MethComp)
> data( ox )
> ox <- Meth( ox, print=FALSE )
> summary( ox )

      #Replicates
Method  1  2  3 #Items #Obs: 354 Values:  min med  max
CO      1  4  56   61   177   22.2 78.6 93.5
pulse   1  4  56   61   177   24.0 75.0 94.0

> par( mar=c(3,3,1,3), mgp=c(3,1,0)/1.6 )
> BA.plot( ox, pl.type="BA",
+         axlim=c(20,100), diflim=c(-30,30) )

> par( mar=c(3,3,1,3), mgp=c(3,1,0)/1.6 )
> BA.plot( ox, pl.type="BA", col.points=gray(0.5), repl.conn=TRUE,
+         axlim=c(20,100), diflim=c(-30,30), col.lines=gray(0.5) )

> par( mar=c(3,3,1,3), mgp=c(3,1,0)/1.6 )
> BA.plot( ox, pl.type="BA", col.points=gray(0.6), repl.conn=TRUE,
+         axlim=c(20,100), diflim=c(-30,30), col.lines=gray(0.6) )
> par( new=TRUE )
> BA.plot( mean(ox), pl.type="BA", col.points="blue", cex=0.5,
+         axlim=c(20,100), diflim=c(-30,30) )
```

Replicate measurements

- ▶ The limits of agreement should still be for difference between future **single** measurements.
- ▶ Analysis based on the **means** of replicates is therefore **wrong**:
- ▶ If the model is:

$$y_{mir} = \alpha_m + \mu_i + a_{ir} + c_{mi} + e_{mir}$$

- ▶ ... then the correct limits of agreement are:

$$\alpha_1 - \alpha_2 \pm 2\sqrt{\tau_1^2 + \tau_2^2 + \sigma_1^2 + \sigma_2^2}$$

Wrong or almost right?

- ▶ $\text{var}(y_{1jr} - y_{2jr}) = \tau_1^2 + \tau_2^2 + \sigma_1^2 + \sigma_2^2$
— note that the term $a_{ir} - a_{ir}$ cancels because we are referring to the **same** replicate.
- ▶ If we are using means of replicates to form the differences we have:

$$\begin{aligned}\bar{d}_i &= \bar{y}_{1i} - \bar{y}_{2i} \\ &= \alpha_1 - \alpha_2 + \sum_r a_{ir}/R_{1i} - \sum_r a_{ir}/R_{2i} \\ &\quad + c_{1i} - c_{2i} + \sum_r e_{1ir}/R_{1i} - \sum_r e_{2ir}/R_{2i}\end{aligned}$$

\Rightarrow

$$\begin{aligned}\text{var}(\bar{d}_i) &= \tau_1^2 + \tau_2^2 + \sigma_1^2/R_{1i} + \sigma_2^2/R_{2i} \\ &< \tau_1^2 + \tau_2^2 + \sigma_1^2 + \sigma_2^2\end{aligned}$$

(Linked) replicates as items

- ▶ If replicates are taken as items, then the differences are:

$$d_{ir} = y_{1ir} - y_{2ir} = \alpha_1 - \alpha_2 + c_{1i} - c_{2i} + e_{1ir} - e_{2ir}$$

- ▶ which has variance $\tau_1^2 + \tau_2^2 + \sigma_1^2 + \sigma_2^2$, and so gives the correct limits of agreement.
- ▶ But the differences are not independent:

$$\text{cov}(d_{ir}, d_{is}) = \tau_1^2 + \tau_2^2$$

- ▶ Negligible if the residual variances are very large compared to the interaction, variance likely to be only slightly downwards biased.

Exchangeable replicates as items?

- ▶ Exchangeable replicates: not clear how to produce the differences with replicates as items.
- ▶ If replicates are paired at random (see the function `perm.rep1`), the variance will still be correct using the model without the $i \times r$ interaction term (a_{ir}):

$$\text{var}(y_{1ir} - y_{2is}) = \tau_1^2 + \sigma_1^2 + \tau_2^2 + \sigma_2^2$$

- ▶ Differences will be positively correlated within item:

$$\text{cov}(y_{1ir} - y_{2is}, y_{1it} - y_{2iu}) = \tau_1^2 + \tau_2^2$$

— slight underestimate of the true variance.

Recommendations

- ▶ Fit the correct model, and get the estimates from that, e.g. by using `BA.est`.
- ▶ If you must use over-simplified methods:
 - ▶ Use linked replicates as item.
 - ▶ If replicates are not linked; make a random linking.
 - ▶ Note: If this give a substantially different picture than using the original replicate numbering as linking key, there might be something fishy about the data.

Further details, see [6].

Haukeland University Hospital, Bergen, Norway

<http://BendixCarstensen.com/MethComp/Courses/Bergen.2014>

(Repro)

Accuracy of a measurement method

(ISO 5625)

- ▶ Repeatability:
The accuracy of the method under exactly similar circumstances; i.e. the same lab, the same technician, and the same day.
(**Repeatability** conditions)
- ▶ Reproducibility:
The accuracy of the method under comparable circumstances, i.e. the same machinery, the same kit, but possibly different days or laboratories or technicians.
(**Reproducibility** conditions)

Quantification of accuracy

- ▶ Upper limit of a 95% confidence interval for the difference between two measurements.
- ▶ Suppose the variance of the measurement is σ^2 :

$$\text{var}(y_{mi1} - y_{mi2}) = 2\sigma^2$$

— standard error of difference: $\sqrt{2}\sigma$

- ▶ Confidence interval for the difference:

$$0 \pm 1.96 \times \sqrt{2}\sigma = 0 \pm 2.772\sigma \approx \pm 2.8\sigma$$

- ▶ This is called the reproducibility coefficient or simply the **reproducibility**.
(2.8 is used as a convenient approximation).

Quantification of accuracy

- ▶ Where do we get the σ ?
- ▶ Repeat measurements on the same item.
- ▶ The conditions under which the repeat (replicate) measurements are taken determines whether we are estimating repeatability or reproducibility.
- ▶ In larger experiments we must consider the **exchangeability** of the replicates — i.e. which replicates are done under (exactly) similar conditions and which are not.

Coefficient of variation

- ▶ Defined as s.d. relative to mean: $CV = \sigma/\mu$
- ▶ Measurements with varying mean and s.d. may still have constant CV.
- ▶ Assumption of s.d. proportional to μ across the range of y , $\text{s.d.}(y) = CV\mu(y)$
— implies that measurements are positive.
- ▶ LoA could be:

$$\mu \pm 2CV\mu$$

- ▶ But what if $CV > 0.5$ — lower bound < 0 ?
- ▶ Immaterial — "2" depends on the degree of confidence chosen anyway.

Coefficient of variation

- ▶ σ proportional to μ
- ▶ \Rightarrow confidence intervals should be multiplicative: $\mu \times \text{erf}$ for some error-factor.
- ▶ Specifically:

$$\text{s.d.}(\log(Y)) \approx \sigma \times \left. \frac{d\log(y)}{dy} \right|_{y=\mu} = \sigma/\mu = CV$$

- ▶ ... so using CV is just doing analysis on the log-scale.

Coefficient of variation

- ▶ CV small:
CV is the same as the s.d. of the log-transformed data.
- ▶ CV large:
CV is **not** same as the s.d. of the log-transformed data.
- ▶ ... but it is the log-transformed analysis that is meaningful.
- ▶ Empirical question if this gives a better model.

A common misconception

There are other approaches that might also be used (e.g., coefficients of variation, item response theory, or the “signal to noise ratio”). [7]¹

- ▶ The authors seem to think that coefficient of variation is another **model**.
- ▶ It is not a different model — just the same model on a transformed **scale**,
- ▶ — focusing on the variance (of the log-transformed data)

Haukeland University Hospital, Bergen, Norway

<http://BendixCarstensen.com/MethComp/Courses/Bergen.2014>

(Lin-bias)

Extension with non-constant bias

$$y_{mir} = \alpha_m + \beta_m \mu_i + \text{random effects}$$

- ▶ There is now a **scaling** between the methods.
- ▶ Methods do not measure on the same scale — the relative scaling is **estimated**, between method 1 and 2 the scale is β_2/β_1 .
- ▶ Consequence: Multiplication of all measurements on one method by a fixed number does not change results of analysis:
 - ▶ The α s & β s are multiplied by the same factor
 - ▶ as is the s.d.s of the variance components for this method.

Variance components

$$y_{mir} = \alpha_m + \beta_m (\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

- ▶ The random effects c_{mi} and e_{mir} have variances specific for each method.
- ▶ Variance of a_{ir} does not depend on m — reporting scaled to each of the methods by the corresponding β_m .
- ▶ Implies that $\omega = \text{s.d.}(a_{ir})$ is irrelevant — the scale is arbitrary.
- ▶ Relevant quantities are $\beta_m \omega$ — the between replicate variation within item **as measured on the m th scale.**

Variance components

Method, Item, Replicate.

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$
$$\text{s.d.}(c_{mi}) = \tau_m$$

- ▶ **Matrix-effect:** Each item reacts differently to each method.
- ▶ If only two methods:
 - ▶ τ_1 and τ_2 cannot be separated.
 - ▶ Variances must be reported on the scale of each method, as $\beta_m \tau_m$.

Variance components

Method, Item, Replicate.

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$
$$\text{s.d.}(a_{ir}) = \omega$$

- ▶ Common across methods — must be scaled relative to the methods.
- ▶ Included if replicates are linked across methods, e.g. if there is a sequence in the replicates.
- ▶ a_{ir} nuisance parameters — $(\mu_i + a_{ir})$ is the “true” value underlying measurements y_{mir} .

Estimation in the extended model

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

- ▶ Not a standard linear mixed model.
- ▶ Does not fit into usual software.
- ▶ Fitted in BUGS, using JAGS via MCmcmc.
- ▶ ...or AltReg — we shall return to this later

How the data is generated I

- ▶ A statistical model is a description of a machinery that may have generated data
- ▶ Illustrate how the various components make up the observed data.

$$y_{mir} = \alpha_m + \beta_m(\mu_i + c_{mi}) + e_{mir}$$

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

Converting between methods

Bendix Carstensen

SAoMCS

19–20 March 2014

Haukeland University Hospital, Bergen, Norway

<http://BendixCarstensen.com/MethComp/Courses/Bergen.2014>

(Convert)

Predicting method 2 from method 1

$$y_{10r} = \alpha_1 + \beta_1(\mu_0 + a_{0r} + c_{10}) + e_{10r}$$

$$y_{20r} = \alpha_2 + \beta_2(\mu_0 + a_{0r} + c_{20}) + e_{20r}$$

↓

$$y_{20r} = \alpha_2 + \frac{\beta_2}{\beta_1}(y_{10r} - \alpha_1 - e_{10r}) + \beta_2(-c_{10} + c_{20}) + e_{20r}$$

The random effects have expectation 0, so:

$$E(y_{20}|y_{10}) = \hat{y}_{20} = \alpha_2 + \frac{\beta_2}{\beta_1}(y_{10} - \alpha_1)$$

- ▶ Intercept: $\alpha_{2|1} = \alpha_2 - \alpha_1 \frac{\beta_2}{\beta_1}$

- ▶ Slope: $\beta_{2|1} = \frac{\beta_2}{\beta_1}$

- ▶ Invariant under linear transform of μ :

$$a + b\mu_i \rightarrow \tilde{\mu}_i \quad \Rightarrow \quad \alpha_m + \beta_m\mu_i \rightarrow \tilde{\alpha}_m + \tilde{\beta}_m\tilde{\mu}_i$$

where: $\tilde{\alpha}_m = \alpha_m - a\beta_m/b$, $\tilde{\beta}_m = \beta_m/b$

- ▶ \Rightarrow the conversion is invariant too:

$$\alpha_{2|1} = \tilde{\alpha}_2 - \tilde{\alpha}_1 \frac{\tilde{\beta}_2}{\tilde{\beta}_1}$$

$$\beta_{2|1} = \frac{\tilde{\beta}_2}{\tilde{\beta}_1}$$

$$y_{20r} = \alpha_2 + \frac{\beta_2}{\beta_1}(y_{10r} - \alpha_1 - e_{10r}) + \beta_2(-c_{10} + c_{20}) + e_{20r}$$

$$\text{var}(\hat{y}_{20}|y_{10}) = \left(\frac{\beta_2}{\beta_1}\right)^2(\beta_1^2\tau_1^2 + \sigma_1^2) + (\beta_2^2\tau_2^2 + \sigma_2^2)$$

The prediction s.d. is:

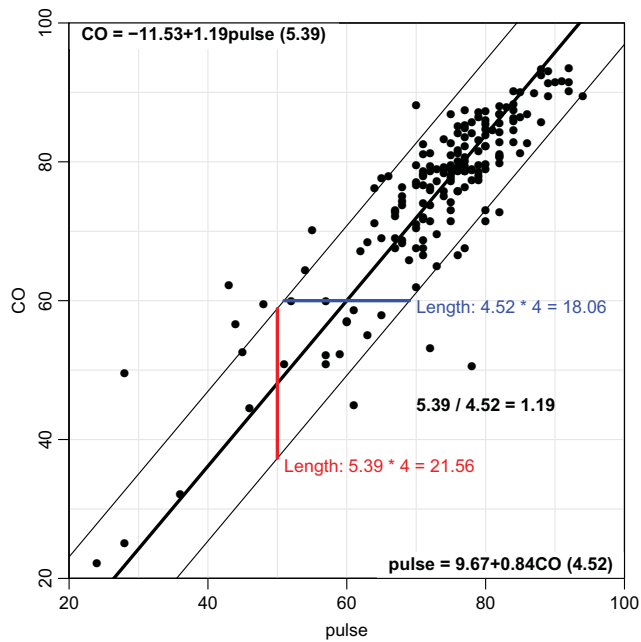

$$\sigma_{2|1} = \sqrt{\left(\frac{\beta_2}{\beta_1}\right)^2(\beta_1^2\tau_1^2 + \sigma_1^2) + (\beta_2^2\tau_2^2 + \sigma_2^2)}$$

If we do the prediction the other way round ($y_1|y_2$) we get the same relationship i.e. a line with the inverse slope, β_1/β_2 .

The width of the prediction interval in this direction is (by permutation of indices):

$$\begin{aligned} \sigma_{1|2} &= \sqrt{(\beta_1^2\tau_1^2 + \sigma_1^2) + \left(\frac{\beta_1}{\beta_2}\right)^2(\beta_2^2\tau_2^2 + \sigma_2^2)} \\ &= \frac{\beta_1}{\beta_2} \sqrt{\left(\frac{\beta_2}{\beta_1}\right)^2(\beta_1^2\tau_1^2 + \sigma_1^2) + (\beta_2^2\tau_2^2 + \sigma_2^2)} = \frac{\beta_1}{\beta_2} \sigma_{2|1} \end{aligned}$$

i.e. if we draw the prediction limits as straight lines they can be used both ways.

What happened to the curvature?

Usually the prediction limits are curved:

$$\hat{y}|x \pm 1.96 \times \hat{\sigma} \sqrt{1 + x'x}$$

In our prediction we have ignored the last term ($x'x$), i.e. effectively assuming that there is no estimation error on $\alpha_{2|1}$ and $\beta_{2|1}$.

```
> set.seed(17676)
> par(mar=c(3,3,1,1),mgp=c(3,1,0)/1.6)
> x <- 1:10
> y <- 3 + 1.6*x + rnorm(x,,6)

+          lwd=c(4,2,2), col="black", lty=1 )
```

Comparing to a gold standard

- ▶ The prediction s.d. is:

$$\sigma_{2|1} = \sqrt{\left(\frac{\beta_2}{\beta_1}\right)^2 (\beta_1^2 \tau_1^2 + \sigma_1^2) + (\beta_2^2 \tau_2^2 + \sigma_2^2)}$$

- ▶ If method 1 is the gold standard (no error), i.e. **assumed**: $\tau_1 = \sigma_1 = 0$
- ▶ Estimate relationship by regressing y_2 on y_1 , deriving τ_2 and σ_2 — standard linear regression.
- ▶ Prediction of y_1 (what would the gold standard give?):
- ▶ Limits for $y_2|y_1$, but used the other way.

Implementation in BUGS/JAGS

Bendix Carstensen

SAoMCS

19–20 March 2014

Haukeland University Hospital, Bergen, Norway

<http://BendixCarstensen.com/MethComp/Courses/Bergen.2014>

(BUGS-impl)

Implementation in BUGS

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

Non-linear hierarchical model:

- ▶ The model is *symmetrical* in methods.
- ▶ Mean is overparametrized.
- ▶ Choose a prior (and hence posterior!) for the μ s with finite support.
- ▶ Keeps the chains nicely in place.

This is the philosophy in the function `MCmcmc`.

Results from fitting the model

The posterior dist'n of $(\alpha_m, \beta_m, \mu_i)$ is singular.

But the relevant translation quantities **are** identifiable:

$$\alpha_{2|1} = \alpha_2 - \alpha_1\beta_2/\beta_1$$

$$\beta_{2|1} = \beta_2/\beta_1$$

— so are the variance components.

Posterior medians used to devise prediction equations with limits.

Implemented model:

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

- ▶ Replicates required in data.
- ▶ **JAGS** (or R2WinBUGS or BRUGS) is required.
- ▶ Dataframe with variables meth, item, repl and y (a Meth object)
- ▶ The function `MCmcmc` writes a BUGS-program, initial values and data to files.
- ▶ Runs **JAGS** and sucks results back in to **R**, and gives a nice overview of the conversion equations.

Implementation in BUGS/JAGS (BUGS-impl)

Haukeland University Hospital, Bergen, Norway

<http://BendixCarstensen.com/MethComp/Courses/Bergen.2014>

(Alt-reg)

Alternating random effects regression

Carstensen [3] proposed a ridiculously complicated approach to fit the model

$$y_{mir} = \alpha_m + \beta_m \mu_i + c_{mi} + e_{mir}$$

based in the observation that:

- ▶ For fixed μ the model is a linear mixed model.
- ▶ For fixed (α, β) it is a regression through 0.

This has be improved by Carstensen in [4]

Alternating random effects regression

The correctly formulated version of the slightly more general model:

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

- ▶ For fixed $\zeta_{mir} = \mu_i + a_{ir} + c_{mi}$ the model is a linear model, with residual variances different between methods.
- ▶ For fixed (α, β) scaled responses y follow a standard mixed model:

$$\frac{y_{mir} - \alpha_m}{\beta_m} = \mu_i + a_{ir} + c_{mi} + e_{mir}/\beta_m$$

Estimation algorithm

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

1. Start with $\zeta_{mir} = \bar{y}_{mi}$.
2. Estimate (α_m, β_m) .
3. Compute the scaled responses and fit the random effects model.
4. Use the estimated μ_i s, and BLUPs of a_{ir} and c_{mi} to update ζ_{mir} .
5. Check convergence in terms of identifiable parameters.

The residual variances

- ▶ The variance components are estimated in the model for the scaled response.
- ▶ The estimation of parameters (α_m, β_m) are not taken into account in the calculation of the residual variance d.f.
- ▶ Hence the residual variances must be corrected *post hoc*.
- ▶ This machinery is implemented in the function `AltReg` in the `MethComp` package.

Transformation of data

Bendix Carstensen

SAoMCS

19–20 March 2014

Haukeland University Hospital, Bergen, Norway

<http://BendixCarstensen.com/MethComp/Courses/Bergen.2014>

(Transform)

If variances are not constant

A transformation might help:

```
> library( MethComp )
> data( ox )
> ox <- Meth( ox )
```

The following variables from the dataframe "ox" are used as the Meth variables:

```
meth: meth
item: item
repl: repl
y: y
```

```
      #Replicates
Method  1  2  3 #Items #Obs: 354 Values:  min med  max
CO      1  4 56   61   177      22.2 78.6 93.5
pulse   1  4 56   61   177      24.0 75.0 94.0
```

```
> DA.reg(ox)
```

```
Conversion between methods:
      alpha  beta  sd.pr beta=1 in(t-f) sl(t-f) sd(t-f) in(sd) sl(sd)

```

```
> round( ftable(DA.reg(ox)$Conv[,,-(1:4)]), 3 )
```

Transformation of data (Transform) 132/ 144

Transformation of data (Transform)

133/ 144

```
> library(MethComp)
> data( ox )
> ox <- Meth( ox )
```

The following variables from the dataframe "ox" are used as the Meth variables:

```
meth: meth
item: item
repl: repl
y: y
```

```
      #Replicates
Method  1  2  3 #Items #Obs: 354 Values:  min med  max
CO      1  4 56   61   177      22.2 78.6 93.5
pulse   1  4 56   61   177      24.0 75.0 94.0
```

```
> system.time( MCox <- MCmcmc( ox, IxR=TRUE ) )
```

Transformation of data (Transform)

134/ 144

Comparison of 2 methods, using 354 measurements on 61 items, with up to 3 replicate measurements, (replicate values are in the set: 1 2 3) (2 * 61 * 3 = 366):

No. items with measurements on each method:

Method	#Replicates			#Items	#Obs: 354	Values:	min	med	max
	1	2	3						
CO	1	4	56	61	177		22.2	78.6	93.5
pulse	1	4	56	61	177		24.0	75.0	94.0

Simulation run of a model with

- method by item and item by replicate interaction:
- using 4 chains run for 2000 iterations (of which 1000 are burn-in),
- monitoring all values of the chain:
- giving a posterior sample of 4000 observations.

Initialization and burn-in:

Compiling model graph
 Resolving undeclared variables
 Allocating nodes
 Graph Size: 2868

Initializing model

Sampling:

	user	system	elapsed
	16.27	0.05	16.39

Transformation of data (Transform)

135/ 144

```
> ( Mox <- MethComp( MCox ) )
```

Conversion between methods:

To:	From:	alpha	beta	sd.pr	in(t-f)	sl(t-f)	sd(t-f)
CO	CO	0.000	1.000	2.553	0.000	0.000	2.553
	pulse	-9.341	1.161	5.263	-8.645	0.149	4.871
pulse	CO	8.045	0.861	4.526	8.645	-0.149	4.864
	pulse	0.000	1.000	5.985	0.000	0.000	5.985

Variance components (sd):

Method	s.d.	IxR	MxI	res
CO	3.706	3.089	1.805	
pulse	3.173	2.647	4.232	

```
> par( mar=c(3,3,1,1), mgp=c(3,1,0)/1.6 )
> plot( Mox, points=TRUE, axlim=c(0,100), xaxs="i", yaxs="i" )
```

Relationships between methods:

CO-pulse = -8.64+0.15(CO+pulse)/2 (4.87)
 CO = -9.34+1.16pulse (5.26)
 pulse = 8.05+0.86CO (4.53)

Transformation of data (Transform)

136/ 144

Transformation of data (Transform)

137/ 144

Using the Transform argument I

```
> system.time( MCox <- MCmcmc( ox, IxR=TRUE, Transform="pctlogit" ) )
```

Comparison of 2 methods, using 354 measurements
on 61 items, with up to 3 replicate measurements,
(replicate values are in the set: 1 2 3)
(2 * 61 * 3 = 366):

No. items with measurements on each method:

Method	#Replicates			#Items	#Obs:	354 Values:	min	med	max
CO	1	4	56	61	177	-1.254049	1.300981	2.666159	
pulse	1	4	56	61	177	-1.152680	1.098612	2.751535	

Simulation run of a model with
- method by item and item by replicate interaction:
- using 4 chains run for 2000 iterations
(of which 1000 are burn-in),
- monitoring all values of the chain:
- giving a posterior sample of 4000 observations.

Initialization and burn-in:
Compiling model graph
Resolving undeclared variables
Allocating nodes
Graph Size: 2869

Transformation of data (Transform)

138/ 144

Using the Transform argument II

Initializing model

Sampling:
user system elapsed
16.12 0.00 16.19

```
> ( Tox <- MethComp( MCox ) )
```

Note: Response transformed by: function (p) log(p/(100 - p))

Conversion between methods:

CO	0.257	0.176	0.13
pulse	0.224	0.154	0.20

Transformation of data (Transform)

139/ 144

Using the Transform argument III

```
> par( mar=c(3,3,1,1), mgp=c(3,1,0)/1.6 )  
> plot( Mox, points=TRUE, axlim=c(0,100), xaxs="i", yaxs="i",  
+       col.lines=gray(0.5), col.points=gray(0.5) )
```

Relationships between methods:
CO-pulse = -8.64+0.15(CO+pulse)/2 (4.87)
CO = -9.34+1.16pulse (5.26)
pulse = 8.05+0.86CO (4.53)

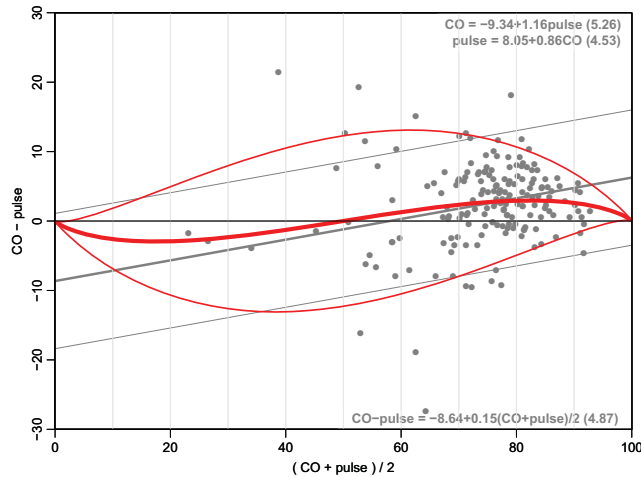

```
> par( new=TRUE )  
> plot( Tox, points=FALSE, axlim=c(0,100), xaxs="i", yaxs="i",  
+       col.lines="red", lwd=c(5,2,2) )
```

Transformation of data (Transform)

140/ 144

Transformation to a Bland-Altman plot

Just convert to the differences versus the averages:

Transformation of data (Transform)

141 / 144

```
> par( mar=c(3,3,1,1), mgp=c(3,1,0)/1.6 )
> plot( Mox, pl.type="BA", points=TRUE, xlim=c(0,100), ylim=c(-30,30),
+       xaxs="i", yaxs="i" )
```

```
Relationships between methods:
CO-pulse = -8.64+0.15(CO+pulse)/2 (4.87)
CO = -9.34+1.16pulse (5.26)
pulse = 8.05+0.86CO (4.53)
```

```
> abline( h=0 )
```

```
> par( mar=c(3,3,1,1), mgp=c(3,1,0)/1.6 )
> plot( Mox, pl.type="BA", points=TRUE, xlim=c(0,100), ylim=c(-30,30),
+       xaxs="i", yaxs="i", col.lines=gray(0.5), col.points=gray(0.5) )
```

```
Relationships between methods:
CO-pulse = -8.64+0.15(CO+pulse)/2 (4.87)
CO = -9.34+1.16pulse (5.26)
pulse = 8.05+0.86CO (4.53)
```

```
> abline( h=0 )
> par( new=TRUE )
> plot( Tox, pl.type="BA", points=FALSE, xlim=c(0,100), ylim=c(-30,30),
+       xaxs="i", yaxs="i", col.lines="red", lwd=c(5,2,2) )
> abline( h=0 )
```
