

Comparing Clinical Measurements

or: **Statistical Analysis of Method Comparison studies**

Bendix Carstensen Steno Diabetes Center, Gentofte,
bxc@steno.dk

ROeS 2013, Dornbirn, Austria
Monday 9th September

<http://BendixCarstensen.com/MethComp/Dornbirn.2013>

What this is about

- ▶ Two (laboratory) methods for measuring the same clinical quantity.
- ▶ Persons are measured with both methods.
- ▶ Scaled measurements (continuous).
- ▶ Errors in both variables.

1 / 125

Glucose measurements

2 / 125

Course outlook

- ▶ **Model** based approach
- ▶ Explicit **parametric** models:
 - ▶ Assumptions are made clear
 - ▶ — relaxing assumptions is clear
- ▶ **Comparison** of methods:
 - can one replace the other?
- ▶ **Conversion** between methods:
 - if measurement is y_1 with method 1, what would it be with method 2?
- ▶ Examples from MethComp package for **R**.
- ▶ Code are in slides

3 / 125

Day schedule 9–12:30

- ▶ One measurement by each method
- ▶ Linear bias
- ▶ Linear s.d.
- ▶ **Break**
- ▶ Replicate measurements, exchangeable / linked
- ▶ **Break** (10:30–11:00)
- ▶ Replicate measurements and linear bias
- ▶ **Break**
- ▶ MCMC methods for estimation of variance components
- ▶ Transformation of measurement scale

4 / 125

Comparing two methods with one measurement on each

Bendix Carstensen

MethComp

Monday 9th September

ROeS 2013, Dornbirn, Austria

<http://BendixCarstensen.com/MethComp/Dornbirn.2013>

(Comp-simple)

Comparing measurement methods

General questions:

- ▶ Are results systematically different?
- ▶ Can one method safely be replaced by another?
- ▶ What is the size of measurement errors?
- ▶ Different centres use different methods of measurement: How can we convert from one method to another?
- ▶ How precise is the conversion?

Comparing two methods with one measurement on each (Comp-simple)

5 / 125

Two methods for measuring fat content in human milk:

The relationship looks like:

$$y_1 = a + by_2$$

Comparing two methods with one measurement on each (Comp-simple)

6 / 125

```
> library(MethComp)
> data( milk )
> milk <- Meth( milk )
```

The following variables from the dataframe "milk" are used as the Meth variables:

```
meth: meth
item: item
y: y
```

```
#Replicates
Method      1 #Items #Obs: 90 Values: min med max
Gerber      45   45   45   0.85 2.67 6.20
Trig        45   45   45   0.96 2.67 6.21
```

```
> par( mar=c(3,3,1,1),mgp=c(3,1,0)/1.6 )
> BA.plot( milk, pl.type="comp", col.line="transparent",
+         lwd=c(3,0,0), axlim=c(1,6)-0.1 )
> abline(0,1)
```

Comparing two methods with one measurement on each (Comp-simple)

7 / 125

Two methods — one measurement by each

- ▶ How large is the difference between a measurement with method 1 and one with method 2 on a (randomly chosen) person?

$$D_i = y_{2i} - y_{1i}, \quad \bar{D}, \quad \text{s.d.}(D)$$

- ▶ 95% prediction interval for the difference between a measurement by method 1 and one by method 2. [1, 2]
- ▶ **Limits of agreement:**

$$\bar{D} \pm 2 \times \text{s.d.}(D)$$

Limits of agreement: Interpretation

- ▶ If a new patient is measured **once** with each of the two methods, the difference between the two values will with 95% probability be within the limits of agreement.
- ▶ This is a **prediction** interval for a single (future) difference.
- ▶ Interpretation requires a **clinical** input: Are the limits of agreement sufficiently narrow to make the use of either of the methods clinically acceptable?

Limits of agreement: Test? **No!**

Testing whether the difference is 0 is a bad idea:

- ▶ If the study is sufficiently small this will be accepted even if the difference is important.
- ▶ If the study is sufficiently large this will be rejected even if the difference is clinically irrelevant.
- ▶ It is an **equivalence** problem:
 1. **Testing is irrelevant:**
 - not interested in the mean difference.
 2. **Clinical input is required.**

Limits of agreement:

Plot differences (D_i) versus averages (A_i).

Comparing two methods with one measurement on each (Comp-simple)

11/ 125

```
> par( mar=c(3,3,1,3), mgp=c(3,1,0)/1.6 )  
> BA.plot( milk, diflim=c(-0.5,0.5), grid=FALSE )
```

Comparing two methods with one measurement on each (Comp-simple)

12/ 125

Model in “Limits of agreement”

- ▶ Methods $m = 1, \dots, M$, applied to $i = 1, \dots, I$ individuals:

$$y_{mi} = \alpha_m + \mu_i + e_{mi}$$

$$e_{mi} \sim \mathcal{N}(0, \sigma_m^2) \quad \text{measurement error}$$

- ▶ Two-way analysis of variance model, with unequal variances in columns.
- ▶ Different variances are not identifiable without replicate measurements for $M = 2$ because the variances cannot be separated.

Limits of agreement:

- Usually interpreted as the likely difference between two future measurements, one with each method:

$$\widehat{y_2 - y_1} = \hat{D} = \alpha_2 - \alpha_1 \pm 2 \text{s.d.}(D)$$

- Convert to prediction interval for y_2 given y_1 :

$$\hat{y}_{2|1} = \hat{y}_2|y_1 = \alpha_2 - \alpha_1 + y_1 \pm 2 \text{s.d.}(D)$$

- Formally, we should replace:

$$2 \rightarrow t_{0.975}(I-1)\sqrt{1+1/I}$$

which equals 2 for $I = 85$

Spurious correlation?

Unequal variances induce correlation between D_i and A_i ; if variances of y_{1i} and y_{2i} are ζ_1^2 and ζ_2^2 respectively:

$$\text{cov}(D_i, A_i) = \frac{1}{2}(\zeta_2^2 - \zeta_1^2) \neq 0 \quad \text{if } \zeta_1 \neq \zeta_2$$

In correlation terms:

$$\rho(D, A) = \frac{1}{2} \left(\frac{\zeta_2^2 - \zeta_1^2}{\zeta_1^2 + \zeta_2^2} \right)$$

i.e. the correlation depends on whether the difference between the variances is large relative to the sizes of the two.

— not really

The variances we were using were the *marginal* variances of y_1 and y_2 :

$$y_{mi} = \alpha_m + \mu_i + e_{mi}$$
$$\text{var}(y_m) = \text{var}(\mu_i) + \sigma_m^2$$

and hence the correlation expression is:

$$\rho(D, A) = \frac{1}{2} \left(\frac{\zeta_2^2 - \zeta_1^2}{\zeta_1^2 + \zeta_2^2} \right) = \frac{1}{2} \left(\frac{\sigma_2^2 - \sigma_1^2}{2\text{var}(\mu_i) + \sigma_1^2 + \sigma_2^2} \right)$$

Hence only relevant if $\text{var}(\mu_i)$ is small relative to σ_1^2 and σ_2^2 .

Not likely in practise.

Introduction to computing

Bendix Carstensen

MethComp

Monday 9th September

ROeS 2013, Dornbirn, Austria

<http://BendixCarstensen.com/MethComp/Dornbirn.2013>

(Intro-comp)

How it works

Example data sets are included in the MethComp package.

The functions in MethComp are based on a data frame with a particular structure; a Meth object:

meth — method (factor)
item — item, person, individual, sample (factor)
repl — replicate (if present) (factor)
y — the actual measurement (numerical)

Once converted to Meth, just use summary, plot etc.

How it looks

```
> subset(ox, as.integer(item)<3)
  meth item repl    y
1    CO     1    1 78.0
2    CO     1    2 76.4
3    CO     1    3 77.2
4    CO     2    1 68.7
5    CO     2    2 67.6
6    CO     2    3 68.3
184 pulse  1    1 71.0
185 pulse  1    2 72.0
186 pulse  1    3 73.0
187 pulse  2    1 68.0
188 pulse  2    2 67.0
189 pulse  2    3 68.0
```

```
> subset(to.wide(ox), as.integer
Note:
Replicate measurements are t
  item repl id    CO pulse
1     1    1 1.1 78.0    71
2     1    2 1.2 76.4    72
3     1    3 1.3 77.2    73
4     2    1 2.1 68.7    68
5     2    2 2.2 67.6    67
6     2    3 2.3 68.3    68
```

Analyses in this course

- ▶ Scatter plots.
- ▶ Bland-Altman plots ($(y_2 - y_1)$ vs. $(y_1 + y_2)/2$)
- ▶ Limits of agreement.
- ▶ Models with constant bias.
- ▶ Models with linear bias.
- ▶ Conversion formulae between methods (single replicates)
- ▶ Plots of conversion equations.
- ▶ Reporting of variance components.

Functions in the MethComp package

5 broad categories of functions in MethComp:

- ▶ Data manipulation — reshaping and changing.
- ▶ Graphical — just exploring data.
- ▶ Simulation — generating datasets or replacing variables.
- ▶ Analysis functions — fitting models to data.
- ▶ Reporting functions — displaying the results from analyses.

Data manipulation functions

- ▶ `Meth` Sets up a `Meth` object — a dataframe in the “long” format, with predefined variable names.
- ▶ `make.repl` Generates a `repl` column in a data frame with columns `meth`, `item` and `y`.
- ▶ `perm.repl` Randomly permutes replicates within (method,item) and assigns new replicate numbers.
- ▶ `to.wide/to.long` Transforms a data frame in the long form to the wide form and vice versa.
- ▶ `Meth.sim` Simulates a dataset (a `Meth` object) from a method comparison experiment.

Graphical functions (basic)

- ▶ `plot.Meth` Plots all methods against all other, both as a scatter plot and as a Bland-Altman plot.
- ▶ `BA.plot` Makes a Bland-Altman plot of two methods from a data frame with method comparison data, and computes limits of agreement.
- ▶ `bothlines` Adds regression lines of y on x and vice versa to a scatter plot.

Analysis functions (simple)

- ▶ `DA.reg`, regresses the differences on the averages. Also regresses the absolute residuals on the averages to check whether the variance is constant. Returns a `MethComp` object.
- ▶ `BA.est` Estimates in the variance components models underlying the concept of limits of agreement, and returns the bias and the variance components. Assumes constant bias between methods. Returns a `MethComp` object.
- ▶ `VC.est` The workhorse behind `BA.est`.
- ▶ `Deming` Performs Deming regression, i.e. regression with errors in both variables.

Analysis functions (general)

- ▶ `MCmcmc` Estimates via BUGS in the general model with non-constant bias (and in the future) possibly non-constant standard deviations of the variance components. Produces an `MCmcmc` object.
- ▶ `AltReg` Estimates via ad-hoc procedure (alternating regressions) in a model with linear bias between methods. Returns a matrix of estimates with the conversion parameters as well as the variance components. Returns a `MethComp` object.

Reporting functions

- ▶ `summary.Meth` Tabulates replicates by methods and items.
- ▶ `print.MethComp` Prints a table of conversion equations based on an estimated model data.
- ▶ `print.MCmcmc` Prints a table of conversion equation between methods analyzed, with prediction standard deviations.
- ▶ `plot.MCmcmc` Plots the conversion lines between methods with prediction limits.
- ▶ `post.MCmcmc` Plots smoothed posterior densities for the estimates.
- ▶ `trace.MCmcmc` Plots the simulation traces from an MCmcmc object.

Non-constant difference

Bendix Carstensen

MethComp

Monday 9th September

ROeS 2013, Dornbirn, Austria

<http://BendixCarstensen.com/MethComp/Dornbirn.2013>

(Non-const)

Limits of agreement — assumptions

- ▶ The difference between methods is constant
- ▶ The variances of the methods (and hence of the difference) is constant.

Check this by:

- ▶ Regress differences on averages.
- ▶ Regress absolute residuals from this on the averages.

Glucose measurements

Non-constant difference (Non-const)

27/ 125

```
> options( width=61 )
> library(MethComp)
> data( glucose )
> gluc <-subset( glucose, type %in% levels(type)[c(2,4)] &
+             meth %in% c("h.cap", "o.cap", "n.plas1"),
+             select=c(2,3,4,6) )
> str( gluc )

'data.frame': 472 obs. of 4 variables:
 $ type: Factor w/ 4 levels "blood","plasma",...: 2 4 2 4 2 4 2 4 2 4 ...
 $ item: num  1 1 1 1 1 1 1 1 2 2 ...
 $ time: num  0 0 30 30 60 60 120 120 0 0 ...
 $ y : num  6.36 5.1 10.3 9.8 13.33 ...

> glu120 <- Meth( subset( gluc, time==120 ), meth="type" )

The following variables from the dataframe
"subset(gluc, time == 120)" are used as the Meth variables:
meth: type
item: item
y: y
#Replicates
Method      1 #Items #Obs: 119 Values:  min med  max
plasma      73   73   73   4.32 7.92 13.42
capil       46   46   46   4.20 7.45 11.80
```

Non-constant difference (Non-const)

28/ 125

```
> par( mar=c(3,3,1,1), mgp=c(3,1,0)/1.6 )
> BA.plot( glu120, wh.comp=2:1, pl.type="comp",
+         col.line="transparent" )
> abline( 0, 1 )
```

Non-constant difference (Non-const)

29/ 125

Glucose measurements

Non-constant difference (Non-const)

30 / 125

```
> par( mar=c(3,3,1,3), mgp=c(3,1,0)/1.6 )  
> BA.plot( glui20, wh.comp=2:1, pl.type="BA" )
```

Non-constant difference (Non-const)

31 / 125

Regress difference on average

$$D_i = a + bA_i + e_i, \quad \text{var}(e_i) = \sigma_D^2$$

If b is different from 0, we could use this equation to derive LoA:

$$a + bA_i \pm 2\sigma_D$$

or convert to prediction as for LoA:

$$y_{2|1} = y_1 + a + bA_i \approx y_1 + a + by_1 = a + (1 + b)y_1$$

Exchanging methods would give:

$$y_{1|2} = -a + (1 - b)y_1$$

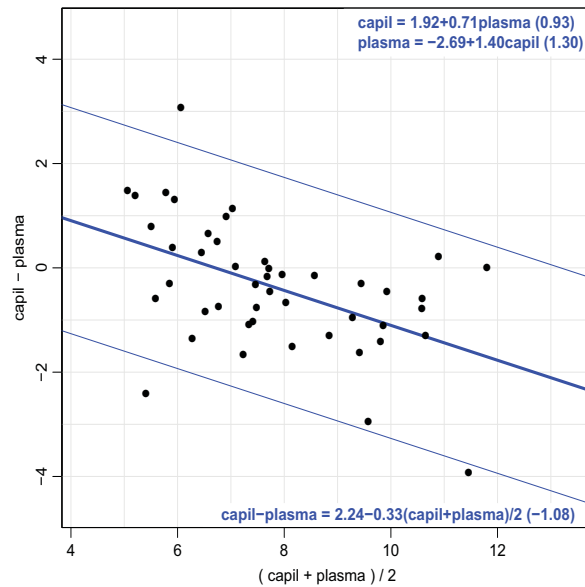

instead of:

$$y_{1|2} = \frac{-a}{1 + b} + \frac{1}{1 + b}y_1$$

Non-constant difference (Non-const)

32 / 125

Variable limits of agreement

Non-constant difference (Non-const)

33/ 125

```
> par( mar=c(3,3,1,3), mgp=c(3,1,0)/1.6 )
> BA.plot( glu120, dif.type="lin",wh.comp=2:1, pl.type="BA" )

> par( mar=c(3,3,1,3), mgp=c(3,1,0)/1.6 )
> BA.plot( glu120, dif.type="lin",wh.comp=2:1, pl.type="BA",
+         eqn=TRUE )
```

Relationships between methods:

```
capil-plasma = 2.24-0.33(capil+plasma)/2 (-1.08)
capil = 1.92+0.71plasma (0.93)
plasma = -2.69+1.40capil (1.30)
```

Non-constant difference (Non-const)

34/ 125

Improving the regression of D on A

$$y_{2i} - y_{1i} = a + b(y_{1i} + y_{2i})/2 + e_i$$

$$y_{2i}(1 - b/2) = a + (1 + b/2)y_{1i} + e_i$$

$$y_{2i} = \frac{a}{1 - b/2} + \frac{1 + b/2}{1 - b/2}y_{1i} + \frac{1}{1 - b/2}e_i$$

$$y_{1i} = \frac{-a}{1 + b/2} + \frac{1 - b/2}{1 + b/2}y_{2i} + \frac{1}{1 + b/2}e_i$$

Details found in [5]

This is what comes out of the functions

`DA.reg` and `BA.plot`.

Non-constant difference (Non-const)

35/ 125

Conversion equation with prediction limits

36/ 125

```
> par( mar=c(3,3,1,1), mgp=c(3,1,0)/1.6 )
> BA.plot( glui20, dif.type="lin",wh.comp=2:1, pl.type="conv",
+         eqn=TRUE )
```

```
Relationships between methods:
capil-plasma = 2.24-0.33(capil+plasma)/2 (-1.08)
capil = 1.92+0.71plasma (0.93)
plasma = -2.69+1.40capil (1.30)
```

Non-constant difference (Non-const)

37/ 125

Why does this work?

The general model for the data is:

$$y_{1i} = \alpha_1 + \beta_1 \mu_i + e_{1i}, \quad e_{1i} \sim \mathcal{N}(0, \sigma_1^2)$$

$$y_{2i} = \alpha_2 + \beta_2 \mu_i + e_{2i}, \quad e_{2i} \sim \mathcal{N}(0, \sigma_2^2)$$

- ▶ Work out the prediction of y_1 given an observation of y_2 in terms of these parameters.
- ▶ Work out how differences relate to averages in terms of these parameters.
- ▶ Then the prediction is as we just derived it.

Non-constant difference (Non-const)

38/ 125

So why is it wrong anyway?

Conceptually:

Once the β_m is introduced:

$$y_{mi} = \alpha_m + \beta_m \mu_i + e_{mi}$$

measurements by different methods are on different scales.

Hence it has formally no meaning to form the differences.

So why is it wrong anyway?

Statistically:

Under the correctly specified model, the induced model for the differences on the averages A_i , these contain the error terms, and so does the residuals.

So the covariate is not independent of the error terms.

Thus the assumptions behind regression are violated.

Then why use it?

- ▶ With only one observation per (method,item) there is not much else to do.
- ▶ If the slope linking the two methods (β_1/β_2) is not dramatically different from 1, the violations are not that big.
- ▶ Implemented in `BA.plot` and in `DA.reg`, which also checks the residuals.

For further details, see [5].

Limits of agreement — assumptions

- ▶ The difference between methods is constant
- ▶ The variances of the methods (and hence of the difference) is constant.

Check this by:

- ▶ Regress differences on averages.
- ▶ Regress absolute residuals from this on the averages.

Non-constant difference (Non-const)

42 / 125

Regressing residuals on average

- ▶ Residuals $\sim \mathcal{N}(0, \sigma^2)$
 \Rightarrow absolute residuals half-normal.
- ▶ Mean of standard half normal is:

$$\int_0^{\infty} x(2/\sqrt{2\pi})\exp(-x^2/2) dx = \sqrt{2/\pi}$$

- ▶ Mean of absolute residuals is $\sigma\sqrt{2/\pi}$
- ▶ Linear relationship of absolute residuals (R_i) to averages (A_i):

$$R_i = a + bA_i \quad \Leftrightarrow \quad \sigma(A) \approx a\sqrt{\pi/2} + b\sqrt{\pi/2}A$$

- ▶ Implemented in DA.reg.

Non-constant difference (Non-const)

43 / 125

```

Non-constant difference (Non-const)

47/ 125

Variable mean and standard deviation

- ▶ 2-step procedure:
 - ▶ Regress D_i on A_i .
 - ▶ Regress R_i (absolute residuals) on A_i
- ▶ Can be done using quadratic rather than linear terms, or even splines.
- ▶ Allows very flexible form of the relationships between differences and averages
- ▶ —and flexible form of the s.d. to the mean.
- ▶ The relationship $D\tilde{A}$ is easily back-transformed to a relationship $y_1\tilde{y}_2$, with prediction intervals.
- ▶ Beware: **over-modelling!**

Non-constant difference (Non-const)

48 / 125

Comparing two methods with replicate measurements

| 3 | 2 | 6.2 | 6.4 |
| 3 | 3 | 6.5 | 6.1 |

Oximetry data; **linked** replicates:

| item | repl | CO | pulse |
|------|------|------|-------|
| 1 | 1 | 77.2 | 73 |
| 1 | 2 | 78.0 | 71 |
| 1 | 3 | 76.4 | 72 |
| 2 | 1 | 68.7 | 68 |
| 2 | 2 | 67.6 | 67 |
| 2 | 3 | 68.3 | 68 |

Extension of the model:

exchangeable replicates

$$y_{mir} = \alpha_m + \mu_i + c_{mi} + e_{mir}$$

$$\text{s.d.}(c_{mi}) = \tau_m \quad \text{— “matrix”-effect}$$

$$\text{s.d.}(e_{mir}) = \sigma_m \quad \text{— measurement error}$$

- ▶ Replicates within (m, i) is needed to separate τ and σ .
- ▶ Even with replicates, the τ s are only estimable if $M > 2$.
- ▶ Still assumes that the difference between methods is constant.
- ▶ Assumes **exchangeability** of replicates.

Extension of the model:

linked replicates

$$y_{mir} = \alpha_m + \mu_i + a_{ir} + c_{mi} + e_{mir}$$

$$\text{s.d.}(a_{ir}) = \omega \quad \text{— between replicates}$$

$$\text{s.d.}(c_{mi}) = \tau_m \quad \text{— “matrix”-effect}$$

$$\text{s.d.}(e_{mir}) = \sigma_m \quad \text{— measurement error}$$

- ▶ Still assumes difference between methods constant.
- ▶ Replicates **linked** between methods:
 a_{ir} is common across methods; first replicate on a person is made under similar conditions for all methods, second too etc.

Replicate measurements

Three approaches to LoA with replicate measurements:

1. Means over replicates within each method by item stratum.
2. Replicates within item are taken as items.
3. Fit the model and use it for the LoA:
 - ▶ The model is a standard linear mixed model with separate variances per method.
 - ▶ The model is fitted using `BA.est(data,linked=TRUE)` — later.

```

Comparing two methods with replicate measurements (comp-repl)

54/ 125

Replicate measurements

- ▶ The limits of agreement should still be for difference between future **single** measurements.
- ▶ Analysis based on the **means** of replicates is therefore **wrong**:
- ▶ Model:

$$y_{mir} = \alpha_m + \mu_i + a_{ir} + c_{mi} + e_{mir}$$

- ▶ In the model the correct limits of agreement would be:

$$\alpha_1 - \alpha_2 \pm 1.96\sqrt{\tau_1^2 + \tau_2^2 + \sigma_1^2 + \sigma_2^2}$$

Wrong or almost right

- ▶ $\text{var}(y_{1jr} - y_{2jr}) = \tau_1^2 + \tau_2^2 + \sigma_1^2 + \sigma_2^2$
— note that the term $a_{ir} - a_{ir}$ cancels because we are referring to the *same* replicate.
- ▶ If we are using means of replicates to form the differences we have:

$$\begin{aligned}\bar{d}_i &= \bar{y}_{1i} - \bar{y}_{2i} = \alpha_1 - \alpha_2 + \frac{\sum_r a_{ir}}{R_{1i}} - \frac{\sum_r a_{ir}}{R_{2i}} \\ &\quad + c_{1i} - c_{2i} + \frac{\sum_r e_{1ir}}{R_{1i}} - \frac{\sum_r e_{2ir}}{R_{2i}} \\ \Rightarrow \text{var}(\bar{d}_i) &= \tau_1^2 + \tau_2^2 + \sigma_1^2/R_{1i} + \sigma_2^2/R_{2i} \\ &< \tau_1^2 + \tau_2^2 + \sigma_1^2 + \sigma_2^2\end{aligned}$$

(Linked) replicates as items

- ▶ If replicates are taken as items, then the calculated differences are:

$$d_{ir} = y_{1ir} - y_{2ir} = \alpha_1 - \alpha_2 + c_{1i} - c_{2i} + e_{1ir} - e_{2ir}$$

- ▶ which has variance $\tau_1^2 + \tau_2^2 + \sigma_1^2 + \sigma_2^2$, and so gives the correct limits of agreement.
- ▶ Differences are not independent:

$$\text{cov}(d_{ir}, d_{is}) = \tau_1^2 + \tau_2^2$$

- ▶ Negligible if the residual variances are very large compared to the interaction, variance likely to be only slightly downwards biased.

Exchangeable replicates as items?

- ▶ Exchangeable replicates: not clear how to produce the differences with replicates as items.
- ▶ If replicates are paired at random (see the function `perm.rep1`), the variance will still be correct using the model without the $i \times r$ interaction term (a_{ir}):

$$\text{var}(y_{1ir} - y_{2is}) = \tau_1^2 + \sigma_1^2 + \tau_2^2 + \sigma_2^2$$

- ▶ Differences will be positively correlated within item:

$$\text{cov}(y_{1ir} - y_{2is}, y_{1it} - y_{2iu}) = \tau_1^2 + \tau_2^2$$

— slight underestimate of the true variance.

Recommendations

- ▶ Fit the correct model, and get the estimates from that, e.g. by using `BA.est`.
- ▶ If you must use over-simplified methods:
 - ▶ Use linked replicates as item.
 - ▶ If replicates are not linked; make a random linking.
 - ▶ Note: If this give a substantially different picture than using the original replicate numbering as linking key, there might be something fishy about the data.

Further details, see [6].

65/ 125

Repeatability and reproducibility

Bendix Carstensen

MethComp

Monday 9th September

ROeS 2013, Dornbirn, Austria

<http://BendixCarstensen.com/MethComp/Dornbirn.2013>

(Repro)

Accuracy of a measurement method

(ISO 5625)

- ▶ Repeatability:
The accuracy of the method under exactly similar circumstances; i.e. the same lab, the same technician, and the same day.
(**Repeatability** conditions)
- ▶ Reproducibility:
The accuracy of the method under comparable circumstances, i.e. the same machinery, the same kit, but possibly different days or laboratories or technicians.
(**Reproducibility** conditions)

Repeatability and reproducibility

66 / 125

Quantification of accuracy

- ▶ Upper limit of a 95% confidence interval for the difference between two measurements.
- ▶ Suppose the variance of the measurement is σ^2 :

$$\text{var}(y_{mi1} - y_{mi2}) = 2\sigma^2$$

— standard error of difference: $\sqrt{2}\sigma$,
confidence interval for the difference:

$$0 \pm 1.96 \times \sqrt{2}\sigma = 0 \pm 2.772\sigma \approx \pm 2.8\sigma$$

- ▶ This is called the reproducibility coefficient or simply the **reproducibility**.
(2.8 is used as a convenient approximation).

Repeatability and reproducibility

67 / 125

Quantification of accuracy

- ▶ Where do we get the σ ?
- ▶ Repeat measurements on the same item (or even better) several items.
- ▶ The conditions under which the repeat (replicate) measurements are taken determines whether we are estimating repeatability or reproducibility.
- ▶ In larger experiments we must consider the **exchangeability** of the replicates — i.e. which replicates are done under (exactly) similar conditions and which are not.

Repeatability and reproducibility

68 / 125

Coefficient of variation

- ▶ Defined as s.d. relative to mean: $CV = \sigma/\mu$
- ▶ Measurements with varying mean and s.d. may still have constant CV.
- ▶ Assumption of proportionality between mean and s.d. across the range of x :
 $s.d.(x) = CV\sigma(x)$
— implies that measurements are positive.
- ▶ LoA could be:

$$\mu \pm 2CV\mu$$

- ▶ But what if $CV > 0.5$ — lower bound < 0 ?
- ▶ Immaterial — depends on the degree of confidence chosen.

Coefficient of variation

- ▶ σ proportional to μ
- ▶ \Rightarrow confidence intervals should be multiplicative: $\mu \times$ erf:
- ▶ Specifically:

$$s.d.(\log(Y)) \approx \sigma \times \left. \frac{d\log(y)}{dy} \right|_{y=\mu} = \sigma/\mu = CV$$

- ▶ Using CV is just using the log-scale:

$$s.d.(\log(X)) = \sigma \frac{d\log(x)}{dx}$$

Coefficient of variation

- ▶ If CV is small:
 CV is the same as the s.d. of the log-transformed data.
- ▶ If CV is large:
 CV is the **not** same as the s.d. of the log-transformed data.
- ▶ But it is the log-transformed analysis that is meaningful.
- ▶ Empirical question if this gives a better model.
- ▶ It is not a different model — just the same model on a transformed scale.

Linear bias between methods

Bendix Carstensen

MethComp

Monday 9th September

ROeS 2013, Dornbirn, Austria

<http://BendixCarstensen.com/MethComp/Dornbirn.2013>

(Lin-bias)

Extension with non-constant bias

$$y_{mir} = \alpha_m + \beta_m \mu_i + \text{random effects}$$

- ▶ There is now a *scaling* between the methods.
- ▶ Methods do not measure on the same scale — the relative scaling is *estimated*, between method 1 and 2 the scale is β_2/β_1 .
- ▶ Consequence: Multiplication of all measurements on one method by a fixed number does not change results of analysis:
 - ▶ The corresponding β is multiplied by the same factor
 - ▶ as is the variance components for this method.

Variance components

Two-way interactions:

$$y_{mir} = \alpha_m + \beta_m (\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

- ▶ The random effects c_{mi} and e_{mir} have variances specific for each method.
- ▶ Variance of a_{ir} does not depend on m — reporting scaled to each of the methods by the corresponding β_m .
- ▶ Implies that $\omega = \text{s.d.}(a_{ir})$ is irrelevant — the scale is arbitrary. The relevant quantities are $\beta_m \omega$ — the between replicate variation within item *as measured on the m th scale*.

Variance components

Method, Item, Replicate.

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$
$$\text{s.d.}(c_{mi}) = \tau_m$$

- ▶ **Matrix-effect:** Each item reacts differently to each method.
- ▶ If only two methods:
 - ▶ τ_1 and τ_2 cannot be separated.
 - ▶ Variances must be reported on the scale of each method, as $\beta_m\tau_m$.

Variance components

Method, Item, Replicate.

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$
$$\text{s.d.}(a_{ir}) = \omega$$

- ▶ Common across methods — must be scaled relative to the methods.
- ▶ Included if replicates are linked across methods, e.g. if there is a sequence in the replicates.
- ▶ a_{ir} nuisance parameters — $(\mu_i + a_{ir})$ is the “true” value underlying measurements y_{mir} .

Extended model

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

- ▶ Not a standard linear mixed model.
- ▶ Does not fit into usual software.
- ▶ Fitted in BUGS, via MCMCmc.
- ▶ ...or AltReg — later

```

> options( width=61 )

MethComp

Monday 9th September

ROeS 2013, Dornbirn, Austria

<http://BendixCarstensen.com/MethComp/Dornbirn.2013>

(Convert)

Predicting method 2 from method 1

$$y_{10r} = \alpha_1 + \beta_1(\mu_0 + a_{0r} + c_{10}) + e_{10r}$$

$$y_{20r} = \alpha_2 + \beta_2(\mu_0 + a_{0r} + c_{20}) + e_{20r}$$

↓

$$y_{20r} = \alpha_2 + \frac{\beta_2}{\beta_1}(y_{10r} - \alpha_1 - e_{10r}) + \beta_2(-c_{10} + c_{20}) + e_{20r}$$

The random effects have expectation 0, so:

$$E(y_{20}|y_{10}) = \hat{y}_{20} = \alpha_2 + \frac{\beta_2}{\beta_1}(y_{10} - \alpha_1)$$

- ▶ Intercept: $\alpha_{2|1} = \alpha_2 - \alpha_1 \frac{\beta_2}{\beta_1}$

- ▶ Slope: $\beta_{2|1} = \frac{\beta_2}{\beta_1}$

- ▶ Invariant under linear transform of μ :

$$a + b\mu_i \rightarrow \tilde{\mu}_i \quad \Rightarrow \quad \alpha_m + \beta_m\mu_i \rightarrow \tilde{\alpha}_m + \tilde{\beta}_m\tilde{\mu}_i$$

where: $\tilde{\alpha}_m = \alpha_m - a\beta_m/b$, $\tilde{\beta}_m = \beta_m/b$

- ▶ \Rightarrow the conversion is invariant too:

$$\alpha_{2|1} = \tilde{\alpha}_2 - \tilde{\alpha}_1 \frac{\tilde{\beta}_2}{\tilde{\beta}_1}$$

$$\beta_{2|1} = \frac{\tilde{\beta}_2}{\tilde{\beta}_1}$$

$$y_{20r} = \alpha_2 + \frac{\beta_2}{\beta_1}(y_{10r} - \alpha_1 - e_{10r}) + \beta_2(-c_{10} + c_{20}) + e_{20r}$$

$$\text{var}(\hat{y}_{20}|y_{10}) = \left(\frac{\beta_2}{\beta_1}\right)^2(\beta_1^2\tau_1^2 + \sigma_1^2) + (\beta_2^2\tau_2^2 + \sigma_2^2)$$

The prediction s.d. is:

$$\sigma_{2|1} = \sqrt{\left(\frac{\beta_2}{\beta_1}\right)^2(\beta_1^2\tau_1^2 + \sigma_1^2) + (\beta_2^2\tau_2^2 + \sigma_2^2)}$$

If we do the prediction the other way round ($y_1|y_2$) we get the same relationship i.e. a line with the inverse slope, β_1/β_2 .

The width of the prediction interval in this direction is (by permutation of indices):

$$\begin{aligned} \sigma_{1|2} &= \sqrt{(\beta_1^2\tau_1^2 + \sigma_1^2) + \left(\frac{\beta_1}{\beta_2}\right)^2(\beta_2^2\tau_2^2 + \sigma_2^2)} \\ &= \frac{\beta_1}{\beta_2} \sqrt{\left(\frac{\beta_2}{\beta_1}\right)^2(\beta_1^2\tau_1^2 + \sigma_1^2) + (\beta_2^2\tau_2^2 + \sigma_2^2)} = \frac{\beta_1}{\beta_2} \sigma_{2|1} \end{aligned}$$

i.e. if we draw the prediction limits as straight lines they can be used both ways.

What happened to the curvature?

Usually the prediction limits are curved:

$$\hat{y}|x \pm 1.96 \times \hat{\sigma} \sqrt{1 + x'x}$$

In our prediction we have ignored the last term ($x'x$), i.e. effectively assuming that there is no estimation error on $\alpha_{2|1}$ and $\beta_{2|1}$.

```
> set.seed(17676)
> par(mar=c(3,3,1,1),mgp=c(3,1,0)/1.6)
> x <- 1:10
> y <- 3 + 1.6*x + rnorm(x,,6)

```

Comparing to a gold standard

- ▶ The prediction s.d. is:

$$\sigma_{2|1} = \sqrt{\left(\frac{\beta_2}{\beta_1}\right)^2 (\beta_1^2 \tau_1^2 + \sigma_1^2) + (\beta_2^2 \tau_2^2 + \sigma_2^2)}$$

- ▶ If method 1 is the gold standard, known without error, *i.e. assumed*: $\tau_1 = \sigma_1 = 0$
- ▶ Estimate relationship by regressing y_2 on y_1 , deriving τ_2 and σ_2 — standar linear regression.
- ▶ Prediction of y_1 (what would the gold standard give?):
- ▶ Limits for $y_2|y_1$, but used the other way.

Alternating regressions

Bendix Carstensen

MethComp

Monday 9th September

ROeS 2013, Dornbirn, Austria

<http://BendixCarstensen.com/MethComp/Dornbirn.2013>

(alt-reg)

Alternating random effects regression

Carstensen [3] proposed a ridiculously complicated approach to fit the model

$$y_{mir} = \alpha_m + \beta_m \mu_i + c_{mi} + e_{mir}$$

based in the observation that:

- ▶ For fixed μ the model is a linear mixed model.
- ▶ For fixed (α, β) it is a regression through 0.

This has be improved in [4]

Alternating random effects regression

The correctly formulated version of the slightly more general model:

$$y_{mir} = \alpha_m + \beta_m (\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

- ▶ For fixed $\zeta_{mir} = \mu_i + a_{ir} + c_{mi}$ the model is a linear model, with residual variances different between methods.
- ▶ For fixed (α, β) scaled responses y are used:

$$\frac{y_{mir} - \alpha_m}{\beta_m} = \mu_i + a_{ir} + c_{mi} + e_{mir} / \beta_m$$

Estimation algorithm

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

1. Start with $\zeta_{mir} = \bar{y}_{mi}$.
2. Estimate (α_m, β_m) .
3. Compute the scaled responses and fit the random effects model.
4. Use the estimated μ_i s, and BLUPs of a_{ir} and c_{mi} to update ζ_{mir} .
5. Check convergence in terms of identifiable parameters.

The residual variances

- ▶ The variance components are estimated in the model for the scaled response. The parameters (α_m, β_m) are not taken into account in the calculation of the residual variance.
- ▶ Hence the residual variances must be corrected *post hoc*.
- ▶ This machinery is implemented in the function `AltReg` in the `MethComp` package.

Variance components

Bendix Carstensen

MethComp

Monday 9th September

ROeS 2013, Dornbirn, Austria

<http://BendixCarstensen.com/MethComp/Dornbirn.2013>

(Var-comp)

Variance components

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

Variance components must be reported on the scale of measurements.

3 variance components / random effects:

- ▶ a_{ir} : between replicates within item, ω^2
 $\beta_m \omega$ is the relevant quantity
 — essentially a nuisance parameter.
- ▶ c_{mi} : matrix effect τ_m^2
 $\beta_m \tau_m$ is the scaling to use.
- ▶ e_{mir} : measurement error, residual variation σ_m^2
 σ_m is on the correct scale.

Variance components - which scale

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

- ▶ Note that c_{mi} — the matrix effect — is multiplied by β_m .
- ▶ Only relevant for $M = 2$, where the random effect cannot be separated between methods.
- ▶ But formally must be on different scales.

Variance components

$$y_{mir} = \alpha_m + \beta_m(\mu_i + a_{ir} + c_{mi}) + e_{mir}$$

The total variance of a measurement is:

$$\sqrt{\beta_m^2 \omega^2 + \beta_m^2 \tau_m^2 + \sigma_m^2}$$

These are the variance components returned by `AltReg` or `MCmcmcm` using `print.MCmcmc` and shown by `post.MCmcmc`.

The following variables from the dataframe
"ox" are used as the Meth variables:
meth: meth
item: item
repl: repl
  y: y
      #Replicates
Method  1  2  3 #Items #Obs: 354 Values:  min med  max
CO      1  4 56   61   177    22.2 78.6 93.5
pulse  1  4 56   61   177    24.0 75.0 94.0

> system.time( MCox <- MCmcmc( ox, IxR=TRUE, n.iter=10000 ) )
```

Comparison of 2 methods, using 354 measurements
on 61 items, with up to 3 replicate measurements,
(replicate values are in the set: 1 2 3)
(2 * 61 * 3 = 366):

No. items with measurements on each method:

| Method | #Replicates | | | #Items | #Obs: | 354 | Values: | | |
|--------|-------------|---|----|--------|-------|------|---------|------|-----|
| | 1 | 2 | 3 | | | | min | med | max |
| CO | 1 | 4 | 56 | 61 | 177 | 22.2 | 78.6 | 93.5 | |
| pulse | 1 | 4 | 56 | 61 | 177 | 24.0 | 75.0 | 94.0 | |

Simulation run of a model with

- method by item and item by replicate interaction:
- using 4 chains run for 10000 iterations
(of which 5000 are burn-in),
- monitoring every 5 values of the chain:
- giving a posterior sample of 4000 observations.

Initialization and burn-in:

Compiling model graph
Resolving undeclared variables
Allocating nodes
Graph Size: 2868

Initializing model

Sampling:

| | user | system | elapsed |
|--|-------|--------|---------|
| | 66.36 | 0.04 | 66.59 |

Variance components (Var-comp)

107/ 125

> *MCox*

Conversion between methods:

| To: | From: | alpha | beta | sd.pred | int(t-f) | slope(t-f) | sd(t-f) |
|-------|-------|--------|-------|---------|----------|------------|---------|
| CO | CO | 0.000 | 1.000 | 2.044 | 0.000 | 0.000 | 2.044 |
| | pulse | -8.313 | 1.146 | 5.205 | -7.748 | 0.136 | 4.851 |
| pulse | CO | 7.254 | 0.873 | 4.540 | 7.748 | -0.136 | 4.849 |
| | pulse | 0.000 | 1.000 | 6.105 | 0.000 | 0.000 | 6.105 |

Variance components (sd):

| Method | IxR | MxI | res |
|--------|-------|-------|-------|
| CO | 3.868 | 3.190 | 1.445 |
| pulse | 3.368 | 2.783 | 4.317 |

Variance components with 95 % cred.int.:

| method | CO | | | pulse | | |
|--------|-----|-------|-------------|-------|-------------|----|
| | qnt | 50% | 2.5% 97.5% | 50% | 2.5% 97.5% | SD |
| IxR | | 3.868 | 3.142 4.557 | 3.368 | 2.744 4.043 | |
| MxI | | 3.190 | 2.214 4.454 | 2.783 | 1.898 3.904 | |
| res | | 1.445 | 0.114 2.653 | 4.317 | 3.645 5.037 | |
| tot | | 5.267 | 4.546 6.201 | 6.184 | 5.541 6.980 | |

Mean parameters with 95 % cred.int.:

| | 50% | 2.5% | 97.5% | P(>0/1) |
|-----------------|--------|---------|--------|---------|
| alpha[pulse.CO] | 7.258 | -1.332 | 14.891 | 0.946 |
| alpha[CO.pulse] | -8.309 | -19.248 | 1.344 | 0.054 |

Variance components (Var-comp)

108/ 125

| | | | | |
|----------------|-------|-------|-------|-------|
| beta[pulse.CO] | 0.873 | 0.772 | 0.988 | 0.012 |
| beta[CO.pulse] | 1.146 | 1.012 | 1.295 | 0.988 |

Note that intercepts in conversion formulae are adjusted to get
conversion formulae that represent the same line both ways,
and hence the median intercepts in the posterior do not agree
exactly with those given in the conversion formulae.
